Foreword

There is no better time than now to invest in health systems. More than two years since the outbreak of COVID-19, societies and economies across the globe are still straining from the impacts of the pandemic. Even the big economies that were presumed to have well-equipped healthcare systems were rendered helpless by a virus that was determined to reach every territory across the globe. We all re-learnt a lesson we had archived in the recesses of our minds: that health security and protecting life must continue to be not only a central state policy, but our societal obsession, too. Equally crucial, we were taught that to manage a health crisis of the magnitude of COVID-19, we must nurture effective and objective emergency communication, adaptive socio-economic behaviour, and the ability to mobilise and deploy resources. For all of this, political and social leadership remains an imperative.

In India, a healthcare delivery system that has historically suffered from ad-hoc regulation, poor monitoring, and modest budgetary allocations, needed to be streamlined rapidly to fight the pandemic. Some states and union territories (UTs) succeeded more than others. For those who did, the key was aligning their health systems with the needs of the population. Today, as the world sees a likely future of recurring infections, state leaders will need to prioritise the building of knowledge systems and investment in human capital and critical infrastructure, and to put into place robust evaluative mechanisms. This will need an across-the-board consensus for action.

This ORF report presents a sub-national analysis of India's health system, which takes into account both the tangible and intangible assets at the state level against the backdrop of the pandemic. This pioneering Health Systems

Resilience Index is composed of five sub-indices that use 33 indicators covering quantifiable aspects of the resources and governance mechanisms that were available to, and were wielded by India's states and UTs. Utilising publicly available data from various government sources, this report gives a clear view of how the states and UTs fared during the 2020 and 2021 waves of COVID-19; while the report ranks states and UTs on the basis of their performance, the aim is to offer a data-driven examination of the gaps in the system that can be addressed to mitigate future crises. This is the time to learn, and more importantly, the time to learn from each other across state boundaries even as we invest in global knowledge and response networks.

As unprecedented as the COVID-19 crisis has been, it will not be the last. We are required to strengthen our health systems and make them harmonious, equitable, and sustainable. It would do us well to start doing this now.

Let me congratulate the lead authors and the ORF research team that have worked on this report. I am sure it will offer valuable inputs to policymakers and to others studying the pandemic.

Dr Samir Saran
President, ORF
July 2022

Executive Summary

1. Introduction

India's COVID-19 battle will be told and retold in the coming years, inspiring both praise for what the country has achieved, and critique for its shortfalls. As India's story continues to unfold, two strands will mould the various assessments. First is India's aggregate performance as a developing economy: It marshalled its meagre resources to respond to the exponential threat of the virus, and was determined, too, to be part of global solutions to this scourge, such as the manufacture and supply of life-saving vaccines. The second, and perhaps even more important story is on ground-zero: In its cities and villages, India's success or failure would be a factor of the leadership and stewardship of Prime Minister Narendra Modi and his team in responding to the crisis, and the commitment of the chief ministers and state functionaries to beef up their health systems and save lives.

Whichever way the India story is told, there are certain truths that cannot be hidden: We need to invest more in our health systems, and acknowledge the stellar role of our frontline workers and formal and informal health sector personnel, as well as India's prowess in certain segments of the medical and health industry.

In this context, it becomes interesting to see how in the country's federal structure (where health is a State subject), the sub-national units—i.e., states and union territories (UTs)—have performed. The present work,

Health Systems Resilience Index: A Sub-National Analysis of India's COVID-19 Response, provides answers to that question. It builds on an earlier report published by the Observer Research Foundation in May 2020. That report, *State of the States: Two Months of the Pandemic*, evaluated India's initial response to the pandemic shortly after the crisis was officially named by the World Health Organization (WHO). Two years since then, this report attempts a more ambitious goal: to devise a unique Resilience Index for the health systems of India's states and UTs.

2. About the Report

The report has two distinct components presenting the state of health systems on the basis of various parameters and reports on the resilience of such systems. It begins with a presentation of individual states and UTs' health profiles, in the context of the pandemic, using publicly available data. All data variables considered for this study were collated from Government of India sources and are available in the public domain. Not a single data has been sourced from a non-governmental origin. On the basis of government data, the report presents a new composite index—one that encapsulates a comprehensive evaluation of the level of resilience of each state and UT that considers the COVID-19 pandemic as a “stress test” for health systems.

3. The Health Systems Resilience Index (HSRI)

3.1. Motivation and need for a composite index for health systems resilience

The prolonged COVID-19 pandemic has served as a “stress test” for India's health systems. Did those systems pass the stress test, or did they fail? More importantly, have those systems been strengthened since, in order for them to become more resilient in the event of subsequent waves of COVID-19 or another health crisis of similar magnitude? These are the key questions that needed to be answered as current health policy literature has not attempted to do so.

It needs to be kept in mind that Health is a State Subject. The Union Government's role is largely prescriptive by way of policy and drug control. However, a disaster of the scale such as that of the pandemic required the Union Government to invoke the Disaster Management Act 2005 and the Epidemic Diseases Act 2020 to intervene.

Yet, that does not take away the responsibilities of the sub-national entities, their initial infrastructure and endowments, and their responses to the outbreak of COVID-19, especially during the disastrous first and second waves.

3.2. Methodology and Data Sources

The index was developed using 33 component indicators, classified into five broad parameters or sub-indices, namely: general health profile; medical infrastructure; technology infrastructure; institutional support; and COVID-19-related health outcomes (see Table ES1). Therefore, the composite index is a combination of initial conditions that are reflective of the health preparedness of a sub-national unit, the response mechanism to the pandemic, and the final outcomes. In another sense, the index is a combination of static variables (those under General Health Profile, Medical Infrastructure, Technology Infrastructure, and the two revenue expenditure variables under institutional support, and the vaccine doses, tests, deaths, peak daily case load under COVID-19 related health outcomes) and dynamic variables (the two related to revenue change under institutional support, and the time taken between the highest peak of daily cases to its 20 percent, time taken between peak positivity rate to fall below 5 percent, days taken to reach benchmark vaccination coverage of 18+ population, and weeks taken to reach benchmark vaccination coverage of 60+ population under COVID-19-related Health Outcomes.)

TABLE ES1: SUB-INDICES, INDICATORS, AND THEIR DATA SOURCES

Sub-Index	Indicators	Data Source
1. General Health Profile	1.1. Households with any usual member covered under a health insurance/financing scheme (%)	NFHS 5 (2019)
	1.2. Children age 12-23 months fully vaccinated based on information from either vaccination card or mother's recall (%)	NFHS 5 (2019)
	1.3. Monthly per capita out-of-pocket expenditure on health as a share of Monthly Per capita Consumption Expenditure (%).	SDG INDEX 2020, NITI Aayog, Government of India
	1.4. Prevalence of NCDs per 100,000 population	Global Burden of Disease Study - India Compare (2019)

2. Medical Infrastructure	2.1. No. of Physicians, Nurses, midwives per 10,000 population	SDG 3 Index 2020, NITI Aayog, Government of India
	2.2. Registered Pharmacists in the State per 10,000 population	National Health Profile 2020
	2.3. COVID-19 Testing Labs per 10,000 population	ICMR, dated: 18th August 2021
	2.4. COVID-19 Sample Collection Centres per 10,000 population	ICMR, dated: 18th August 2021
	2.5. Covid Beds per 10,000 population	Various sources include state NHM/HFWD/COVID-19 Dashboards, dated: August 2021
	2.6. Dedicated Covid Hospitals (DCHs) per 10,000 population	Lok Sabha unstarred question no. 952, dated: 16th September 2020
	2.7. Dedicated Covid Health Centre (DCHC) per 10,000 population	Lok Sabha unstarred question no. 952, dated: 16th September 2020
	2.8. Dedicated Covid Care Centre (CCC) per 10,000 population	Lok Sabha unstarred question no. 952, dated: 16th September 2020
	2.9. Vaccination Sites per 10,000 population	CoWIN DASHBOARD
	2.10. No. of Ventilators per 10,000 population	Rajya Sabha unstarred question no. 2518, dated: 5th August 2021
	2.11. No. of blood banks per 10,000 population	Lok Sabha starred question no. 173, dated: 30th July 2021.
3. Technology Infrastructure	3.1. No. of mobile connections per 100 people	SDG Index 2020, NITI Aayog, Government of India
	3.2. No. of Internet Subscribers per 100 people	SDG Index 2020, NITI Aayog, Government of India
	3.3. Data Reporting Scores	Various State Government Portals/Dashboards
4. Institutional Support	4.1. Revenue Expenditure (2. Medical and Public Health) per 10,000 population	State Finances: Study of Budgets (2020), Reserve Bank of India
	4.2. Revenue Expenditure (3. Family Welfare) per 10,000 population	State Finances: Study of Budgets (2020), Reserve Bank of India
	4.3. Percentage change in revenue expenditure on health in 2020-21(RE) over 2019-20 (RE)	State Finances: Study of Budgets (2020), Reserve Bank of India
	4.4. Percentage change in revenue expenditure on health in 2021-22(BE) over 2019-20 (RE)	State Finances: Study of Budgets (2020), Reserve Bank of India

5. COVID-19-related Health Outcomes	5.1. Vaccine Doses per 100,000 population	COVID19 BHARAT Dashboard, dated: 30th November 2021
	5.2. Tests per 100,000 population	COVID19 BHARAT Dashboard, dated: 30th November 2021
	5.3. Deaths per 100,000 population	COVID19 BHARAT Dashboard, dated: 15th December 2021
	5.4. Cases per 100,000 population	COVID19 BHARAT Dashboard, dated: 30th November 2021
	5.5. Peak daily caseload per 100,000 population (7-day average)	COVID19 BHARAT Dashboard, dated: 30th November 2021
	5.6. Time taken between the highest peak of daily cases to its 20% (7-day average)	COVID19 BHARAT Dashboard, dated: 30th November 2021
	5.7. Time taken between peak positivity rate to fall below 5% (7-day average)	COVID19 BHARAT Dashboard, dated: 30th November 2021
	5.8. Distributional gap between highest and lowest vaccine coverage per 1000 population (district-wise)	CoWIN Dashboard, dated: 31st October 2021
	5.9. Days taken to reach benchmark vaccination coverage of 18+ population	COVID19 BHARAT Dashboard, dated: 30th November 2021
	5.10. Weeks taken to reach benchmark vaccination coverage of 60+ population	CoWIN Dashboard, dated: 30th November 2021
	5.11. Gender gap in vaccination coverage (female-to-male ratio) per 18+ 100,000 population	CoWIN Dashboard, dated: 30th November 2021

All the indicators use government data as their primary sources. Even the *COVID19 Bharat Dashboard* collates data from governmental sources. All the indicators were normalised and scale biases were removed. The weights were assigned at two stages: at the level of the individual parameters, Principal Component Analysis (PCA) was conducted with 33 component indicators; in the second stage, weights were dictated by informed arbitrariness. The combination helped in simultaneously capturing the variations in capacities and performances of health systems across the various sub-national entities (See Annexure II for further details on data sources and the methodology).

3.3. Key Findings

The detailed findings on the relative performances of the states and UTs are available in section 3 of this volume. Other details on the methodology and results on indicators are provided in Annexures 2 and 3. Some of the key findings are as follows:

1 In terms of the composite scores of HSRI, Goa ranks at the top of all small states, Himachal Pradesh above all large states, and Lakshadweep among the UTs.

2 There is a significant difference between the average level of resilience in health systems among the states and the UTs, with the UTs performing better (and the difference is found to be statistically significant at 1% level).

3 States and UTs with higher per-capita income levels are significantly more resilient to combat a potential new wave of the pandemic or any other health crisis of similar magnitude, than the poorer regions.

4 Meghalaya has done exceedingly well in the domain of institutional support to the health sector. Himachal Pradesh and Sikkim also did relatively well among the remaining states, followed by other small states like Tripura, Goa, and Mizoram. Jammu & Kashmir leads among the UTs.

5

Himachal Pradesh, among the large states, and small states like Goa and Tripura have done better than other states in the management of COVID-19-related Health Outcomes. Among UTs, Lakshadweep and Andaman and Nicobar Islands show noteworthy results, even outperforming all states.

6

Tamil Nadu and Chhattisgarh (among the larger states) and Goa (among the small states) have the best records in their General Health Profile; among the UTs, Dadra & Nagar Haveli and Daman & Diu are the leaders. A notable aspect is that a high score on General Health Profile has not ensured a high score on COVID-19-related health outcomes for the larger states; rather the pattern is quite the opposite. In Medical Infrastructure, smaller states such as Arunachal Pradesh, Sikkim, and Mizoram have the best population-level services as do larger states like Kerala and Maharashtra. Among UTs, Lakshadweep is most equipped.

7

Goa, among the small states and Tamil Nadu and Kerala, among the large states fulfill the most number of criteria for Technology Infrastructure. Delhi leads among the UTs.

Table ES2 shows the HSRI scores and rankings.

TABLE ES 2: HEALTH SYSTEMS RESILIENCE INDEX SCORES AND RANKING

4. Summing-up

More than two years since the first cases of COVID-19 infections were reported in India, the country is now in the midst of recurring infections. Armed with scientific knowledge—not only of the virus that causes COVID-19 but of life-saving vaccines as well—India must, more crucially now than ever, fill the yawning gaps in the country's health systems. This task will be possible through better data infrastructures to drive policy, and an aggressive push towards Universal Health Coverage. Given that India opted for a phased vaccination process beginning with the most vulnerable groups of the population, the figures of 73.5 percent with a single dose and 69 percent fully vaccinated at the time of finalising this report are indeed remarkable. The following months will see the step-by-step deployment of booster doses for India's remaining population.

The imperative is a collective and targeted effort to scale the immunisation initiative while adhering to COVID-19-appropriate behaviour as a population. India must learn from the past three waves and ramp up investments in health and develop sound strategies for expected future waves. Scientific endeavours and behavioural changes are also essential to minimising the impacts of another sudden increase in infections, and even deaths. The past two years of battling the pandemic forced our health systems to a redesign. Today, as new emergencies emerge in a matter of days, key will be the readiness of systems to respond and mobilise resources efficiently.

This report aims to help light the way for India. Utilising a Resilience Index for States and UTs, this study offers insights into the state of the country's health systems at a disaggregated sub-national level, and the parameters that need to be addressed in the short term. This assessment should pave the path for more researchers and scholars to conduct further research in the domain of comparative spatial assessments, and probe the resilience of health systems to shocks. A similar exercise can be undertaken at the global, local, and micro-levels, to determine the effectiveness of existing healthcare ecosystems in responding to various crises.

This report should prove useful for decision-makers as it creates a framework for understanding what works and what does not, and therefore can guide necessary course-correction along the way. The public, too, would benefit from this report as they seek to engage with India's democratic architecture.

1

Introduction

In January 2020, as the world heard the first reports of the novel coronavirus, the medical community had little data with which to formulate responses that could alter the rapid trajectory of what was then an epidemic. Shortly thereafter, in March, the World Health Organization (WHO) declared the outbreak of SARS-CoV-2 a pandemic, and countries immediately implemented lockdowns and restrictions on movement. In India, the first two months of the pandemic saw over 80,000 cases and 2,700 deaths despite a country-wide lockdown from late March.¹ It was at the time that ORF released its report, *State of the States: Two Months of the Pandemic*, which analysed, with the help of emerging data and anecdotal evidence, the initial impact of COVID-19 on India. The key priority then was to delay the spread of infection until health systems could be reinforced and resources ramped up to handle the outbreak.

It helped that the number of medical seats in the country had been increased in recent years—this eased the human resource constraints during the pandemic, as India roped in trainee doctors and medical students to work on the frontlines. Indeed, the last decade saw public investments being channeled to the country's tertiary healthcare sector—in particular, in the supply of health workforce: between 2014 and 2019, there was a 47-percent increase in the number of government medical colleges, and a 33-percent rise in private medical colleges. The number of undergraduate medical seats also saw a jump of 48 percent, from 54,348 in the academic year 2014-15 to 80,312 in 2019-20. While India was expanding the number of seats in government medical colleges, it was also leveraging the private sector to fill gaps in personnel and healthcare delivery.²

Over the past decades, India's health outcome indicators have shown consistent improvement, much of it being achieved despite inadequacies in both policy attention and financing. When the National Health Policy 2017 set a target of allotting 2.5 percent of GDP to government expenditure in health by 2025, most analysts were of the view that the goal was highly ambitious. The next three or so years will reveal whether India reaches that target, and if the COVID-19 pandemic will prove to be a motivation. The Union budget of 2021 announced a new centrally sponsored scheme, the PM Atma Nirbhar Swasthya Bharat Yojana with an outlay of INR 64,180 crores over six years, aimed at developing the capacities of primary, secondary, and tertiary care systems and strengthening capacities from detection to cure.³ However, despite such schemes and the financing of the massive COVID-19 vaccination and screening efforts, the health sector outlays have remained low even during the pandemic years. Even the 2022 Union budget—which provides that the outlay for capital expenditure be enhanced by 35.4 percent from INR 5.54 lakh crore last year to INR 7.50 lakh crore, left the health sector largely untouched.⁴

Government agencies at the forefront of the COVID-19 battle have had to do with the limited resources at their disposal. In April 2020, the Ministry of Health and Family Welfare instituted a three-tier COVID-19 Treatment system to facilitate triaging and thereby maximise constrained supplies.⁵ The first line of testing and detection was assigned to Fever Clinics or local health centres. Suspect or positive patients then moved through the bottom-up, three-tiered structure, from COVID-19 Care Centres to Dedicated COVID-19 Hospitals. Care Centres ensured bigger spaces for isolating both symptomatic and asymptomatic, very mild cases. Tier-2, Dedicated COVID-19 Health Centres are for mild to moderate cases, and the most severe, symptomatic cases were referred to Dedicated COVID-19 Hospitals.

While most states have followed the three-tier structure, some like Kerala have added further levels of management based on criteria such as space for isolation and need for medical monitoring. Meanwhile, a number of states have not set up Fever Clinics at all. Delhi, for instance, decided to employ its own network of Mohalla clinics for preliminary diagnosis and surveillance.

At the time of writing this report, almost 500 million COVID-19 cases have been confirmed globally. India has recorded nearly 42 million of these cases, amounting to about 31,000 cases per million people. The country officially recorded close to 370 deaths per million population. It ranks much lower in both cases and deaths when compared to advanced economies, with notably smaller countries facing a bigger burden on its population-level impact.

FIGURE 1: CUMULATIVE CONFIRMED COVID-19 CASES PER MILLION ACROSS THE WORLD**Cumulative confirmed COVID-19 cases per million people**

Due to limited testing, the number of confirmed cases is lower than the true number of infections.

ORF's own research has catalogued India's dogged efforts to manage the COVID-19 crisis.⁸ India's performance becomes even more remarkable with the massive vaccination drive that covered the largest numbers of population in the shortest period of time. Indeed, on some parameters, India has performed better than certain developed nations that claim to have far superior infrastructure and higher healthcare spending (see Figures 1 and 2, and the vaccination numbers).

India has vaccinated 73.5 percent of its population with a single dose, and 69 percent are fully vaccinated. These figures become more notable when compared to a country like the US, for example, whose size is one-fourth that of India's but has fully vaccinated a lower 66 percent of its population. The ensuing months will witness how India fares in the step-by-step deployment of booster doses for the remaining population.

At the same time, however, the apparent success story at the macro-level is not reflective of the nation's chequered pandemic journey: a pathway fraught with tremendous challenges at various points.

India began with a degree of success in mid-2020 because of the swift lockdowns and focused promotion of appropriate COVID-19 behaviour such as regular handwashing, the wearing of masks, and physical distancing. Eventually, restrictions were eased, and the first wave peaked in September 2020. The sharp rise in cases was attributed to poor adherence to masking and appropriate behaviour during the festive season. Cases and deaths would thereafter fall sharply, until a massive second wave in April and May 2021 ended the notion that India had been able to contain the pandemic and the crisis had met its end. The degree of transmission was so intense that the sero-positivity rate increased from 24.1 percent in January 2021 to 67.6 percent in July 2021.⁹ By early May, the death rate had spiked to almost 4,000 people every day.

As steep as these numbers are, however, they are possibly still higher on the ground.¹⁰ The under-counting could be the result of a number of reasons: sub-national discrepancies in scientific standards and definitions; delayed penetration of COVID-19-related preventive services into sub-urban and rural areas; and weak data and communication systems. Evidence suggests, for example, that socially vulnerable populations like women and the poor are often left out of surveillance simply because the health-seeking behaviour of these groups are unaccounted for in planning.¹¹

After the cruel second wave, there have been efforts to calculate “excess” deaths during the pandemic. A *Lancet study* estimates 4.07 million excess deaths in India compared to the official number of half a million between January 2020 and December 2021.¹² WHO’s recent estimates show a similar statistic.¹³ Computations by Indian scholars, too, have suggested excess deaths to be nearly eight times the official figure.¹⁴ Further, a model by *The Economist* puts excess deaths in India between 1.9 million and 9.7 million by end-2021.¹⁵ The range of these estimates is wide, owing to uncertainty about the quality of both data sources and assumptions.¹⁶ The Union Government quickly denied the estimates, because all the models are based on a host of hypothetical assumptions of conditionalities, and their functional forms largely deviate from real-life conditions.

Recounting and adding backlogs are not easy tasks, given the varying degrees of institutionalisation of medical care across the country and the changing definitional guidelines for classifying deaths due to COVID-19. According to ORF’s *COVID-19 Tracker*, about 86,000 deaths have been added as backlogs¹⁷ between June 2021 and March 2022—or about 16 percent of all reported COVID-19 deaths in India today.¹⁸ However, only 19 states and UTs ever reported backlogs in deaths. Bihar and Kerala added more than 50 percent of all their COVID-19 deaths through backlog counting and compensation appeals.¹⁹ Other states like Karnataka, Madhya Pradesh, Maharashtra, and Tamil Nadu have also been consistently adding numbers to their logs. Media reports also point to much higher numbers of *ex-gratia* claims for compensation of COVID-19 deaths, compared to the reported numbers.²⁰

Yet, 2021 was not only about rapid transmission dynamics and mounting deaths; it was also the year that the vaccination rollout was initiated. The drive faced acute shortages shortly after being started in January 2021, but eventually picked up pace and accelerated in the latter part of the year. India is currently using four vaccines, and ten more have received emergency approvals.²¹ As of 15 March 2022, more than 80 percent of the population above 45 years of age, and 75 percent of the 18-44 cohort, are fully vaccinated. The coverage for the younger group of 15- to 17-year-olds is at 46 percent. At its current levels of mass inoculation, India has come closer to community-level protection as milder infections continue to help build natural immunity against the virus. Figure 3 shows the patterns of this attuned immunity—even through the Omicron-led third wave, hospitalisation and deaths remained largely consistent and low.

FIGURE 3: DAILY NEW CONFIRMED COVID-19 DEATHS IN INDIA

Daily new confirmed COVID-19 deaths per million people

7-day rolling average. Due to varying protocols and challenges in the attribution of the cause of death, the number of confirmed deaths may not accurately represent the true number of deaths caused by COVID-19.

Our World
in Data

Source: Our World in Data²⁵ (collated data from www.mygov.in)

This report offers a unique *Health Systems Resilience Index* that measures how, and to what extent states and regions across India have adapted to the COVID-19 crisis and grew in capacities over the past year. Each state and UT is profiled in three broad areas: (a) their current health profile—which uses indicators such as demographics (as per the 2021 projections), 2020 ranking in Sustainable Development Goal 3 (Good Health and Well-being), regular vaccination coverage for under-fives, out-of-pocket health expenditure, and causes of mortality; (b) COVID-19 preparedness and response (which offers a population-level description of the states' medical infrastructure, technological response, and government investments); and (c) COVID-19 cases, deaths, tests, and vaccination.

While the initial research for this study was conducted in early 2021, the last leg of the data collection was ended in November-December 2021. The development of the index, and the writing and production of this report was all done in early 2022, as the highly transmissible Omicron wave of COVID-19 was receding in India, even as the country continued to reel from its impacts. Unlike the Delta-led second wave, which was gradual in its

ebbs and flows and yet far more fatal, the third wave was rapid to rise and equally quick to fall, with considerably lower incidence of hospitalisation and less fatalities, too.²³

The daily reported cases have come under 5,000 at the time of writing this report, and life is slowly getting back to normal as children have gone back to school and even recreational facilities are operating at full capacity. The high level of vaccine coverage and infection-induced natural immunity has kept fatalities low during the third wave led by the Omicron variant and its sub-lineages. Despite the rapid pace of vaccination, subsequent waves of the virus may still recur in the coming months, given the very nature of a pandemic—i.e., prolonged, with repeated waves of infections. It is vital to reassess the situation and re-strategise the country's preparedness.

India has historically suffered from a scarcity of timely and quality data that could inform crucial decisions on healthcare, though the situation has started improving over the last decade. Optimally utilising available data sources, this report offers a data-driven perspective of the performance of India's 28 states and eight UTs during the first two years of the COVID-19 pandemic. It proceeds from the assumption that because Health is a State subject, policies and strategies are planned and executed according to each State's priorities. State capacities and instruments mediate the health sector's financing and governance capabilities, and programme implementation may vary significantly across different states.

In practice, the Union Government has so far played a largely prescriptive role through policy and drug control. But COVID-19 was an exogenous shock that disrupted the fundamentals of the socio-economic architecture of the global economy, as well as those of individual countries, including India's. The sheer scale of the pandemic required the Union Government to invoke the Disaster Management Act 2005 and the Epidemic Diseases Act 2020. That does not take away the responsibilities of the sub-national entities, their initial infrastructure and endowments, and their responses to the outbreak, especially during the disastrous first and second waves.

Meanwhile, there is a view that both the states and the Centre should have legislative powers over healthcare, and in 2019, the High-Level Group on Health constituted under the Fifteenth Finance Commission made precisely this recommendation—i.e., shifting healthcare under "Concurrent Subjects".²⁴ While the implementation of such a recommendation is pending, any assessment of crisis response is best conducted at the sub-national level. The question remains as to how, in India, "cooperative federalism" can

minimise “conflictual federalism” and bring the pandemic under control.²⁵ A comparative analysis of the prospects of India’s states and UTs confronting the challenges of a likely next COVID-19 wave—or another health crisis of similar magnitude—can guide policymakers towards an efficient roadmap.

Notes on Structure, Methodology, and Sources

This report is divided into four main sections: Following the Introduction, Section 2 provides an overview of individual states and UTs; Section 3 introduces the Health Systems Resilience Index, and ranks the states and UTs on a comparative scale of quantifiable indicators within specific themes to assess their respective health systems. Section 4 concludes the report.

Section 2 offers the reader a comprehensive view of the performance of each state. The elements in the state profiles include other parameters that were not available yet at the time of publication of ORF’s first *State of the States* report. These include the numbers of COVID-19 dedicated three-tier health facilities and beds, testing laboratories, and sample collection centres; the technological innovations and investments; as well as parameters on data reporting and granularity.

Each state and UT profile is divided into three sections: general health; COVID-19 preparedness; and government response. The report provides graphical representations of COVID-19 trends and preventive measure of cases, deaths, tests and vaccinations over a span of 20 months. The COVID-19 statistics were culled from a credible, volunteer-driven data platform, *COVID19india* (later continued by COVID19bharat collective), which collates numbers from information bulletins officially released by the respective state governments or their health ministries.

The General Health Profile of the state or UT includes indicators such as age-wise demographics, population density, regular immunisation coverage, out-of-pocket expenditure in health, insurance coverage, top causes of mortality, death rates – both general and related to COVID-19, and per capita revenue expenditure of the state for medical and public health and family welfare. To provide already established scales of evaluation for states’ performances, the report also uses the Bare Necessities Index (Economic Survey 2020, Ministry of Finance) and the SDG 3 India Index for Good Health and Well-being (2020). The scales cover a wide range of social determinants of health.

Immunisation programmes and health spending are discussed as well, using data from the National Family Health Survey 5 (2019-20). Per capita out-of-pocket health expenditure data has been sourced from NITI Aayog's SDG Index 2020.

It is well-established that comorbidities are significant catalysts of mortality and morbidity in COVID-19 infections. While there is a range of medical conditions to study in this spectrum, the researchers have chosen Diabetes and Kidney Diseases, Neoplasms (Cancers), Respiratory Infections and TB, and Cardiovascular Diseases—this is because these diseases cover a gamut of known leading non-communicable diseases for which proper treatment is crucial. The data on the prevalence of such NCDs and the death rates have been taken from a pre-COVID-19 period (2019)—to reflect the pre-existing risk factors in the respective states. The data is sourced from the *Global Burden of Disease: India Compare Study (2019)* by Institute for Health Metrics and Evaluation (IHME) and Public Health Foundation of India (PHFI). Moreover, these comorbidities are more predominant among certain age groups who are thereby more vulnerable to a contagion. Therefore, an age-wise composition of the state's population has been computed in accordance with the government's vaccine policies of under-18 years, 18-44 years, 45-60 years, and 60+ years age groups. The distribution has been computed by the research team using estimates from the Census 2021 projection of population, a detailed process of which is discussed in a latter section of this report.

The section on Preparedness and Response focuses on Medical and Technological efforts to leverage better COVID-19 management. It covers human resources, the physical infrastructure of hospitals, health centres, care centres, laboratories, and vaccination sites, as well as the technological groundwork and initiatives unique to each state and UT. The SDG Index provides the number of doctors, midwives, and nurses, while the National Health Profile (2020) provides the number of registered pharmacists within the state or UT.

The technological response was chosen for this section because the pandemic necessitated a push towards adopting new technologies. The idea was to explore whether the innovative solutions being brought to these areas truly benefit these populations. There has been a historical mismatch between the digital skills across gender, class, caste, and rural-urban divide in the country. At the same time, data is scanty on how these new technologies have been adapted and if the target populations are able to access them.

The crisis also pushed governments to creatively leverage existing technologies like IVRS, Geo-tagging, Geo-fencing, and GPS, while advancing towards more cutting-edge innovations in Machine Learning and Artificial Intelligence to ease the burden on their human resources. These new technologies, in the past two years, were adapted and implemented aggressively for better surveillance and monitoring, contact-tracing, information dissemination, diagnostics, and remote assistance. Since these are essential platforms for multi-sectoral interactions with the health system for better management, this section puts into perspective the overall numbers of mobile-phone and internet users in the state or UT. This can help assess current connectivity capacities and the reach of state-led technology initiatives in the grassroots.

All these parameters need government support to take effect. Therefore, 'Institutional Support' focuses on budgetary allocations and dedicated COVID-19 management and related financing from the 2021-22 Budgets. It gives a picture of the state's pandemic governance priorities and post-pandemic plans. For individual state profiles, the budget highlights have been collated from Budget documents and mainstream media reports.

The third section of this report introduces the Health Systems Resilience Index. The resilience index is a composite measure comprising five sub-indices based on the elements discussed in Section 1. The context for the development of the index, along with its structure and methodology, is discussed in detail later in the report; more information is provided in the Annexure.

Much of the data is from the period between the second and third waves from August and November 2021. By then, the health facilities were less overwhelmed, and temporary setups were reduced, compared to April-May 2021 at the peak of the second wave. The state-wise graphical representations of COVID-19 statistics—Cases, Deaths, Tests, and Vaccinations—range from May 2020 to December 2021.

ORF exerted its best efforts to source information only from verified government sources. All data variables considered for this study have Government of India sources as their fundamental origin and are available in the public domain. Not a single data has been sourced from a non-governmental origin. On the basis of such data, the report presents a new composite index—one that encapsulates a comprehensive evaluation of the level of resilience of each state and UT that considers the COVID-19 pandemic as a “stress test” for health systems. A detailed list of references and their limitations is given in Annexure I. The report closes with a comparative analysis involving the states and the UTs, based on their average levels of preparedness and across different levels of per-capita incomes.

GOVERNMENT AND NON-PROFIT ORGANISATION INITIATIVES

1. **Indore 311 Application:** The application, which existed earlier, was repurposed by the MP government to assist in managing asymptomatic covid patients. It enables patients in home isolation to monitor their oxygen level and pulse rate by a pulse oximeter. The patients are monitored by a team of doctors at the IMA (Indore Medical Association) control room, and their movement around their houses is also tracked.²
2. **Vizbee:** A startup, used drones to conduct sanitization in large areas as well as for surveillance.³
3. **Healthquik:** A mobile application developed to map the location of COVID-19 suspects in Bhopal, to be able to view hotspots as well as to understand the contact history of patients.⁴
4. **The Kabadiwala⁵:** A waste management startup, repurposed its operation to use GPS-based technology to deliver food supplies with over 200 vehicles.

GOVERNMENT INVESTMENTS IN HEALTH (2021-22 BE)

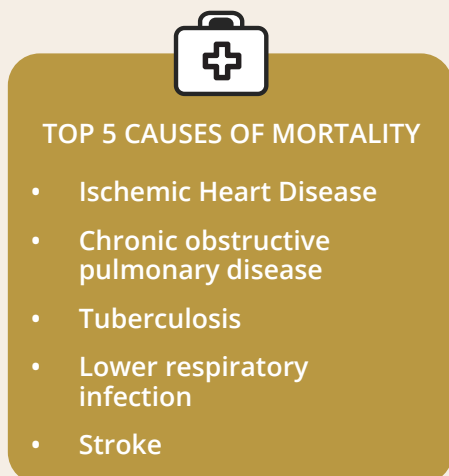

HIGHLIGHTS

- The state will provide free COVID-19 vaccines for all adults and has allocated INR 500 M to procure these vaccines.
- The state has allocated INR 53,950 M under the National Rural Health Mission.
- INR 50,850 M has been provided to construct medical colleges in 39 districts and create diagnostic infrastructure for primary healthcare facilities.

the first part of the paper, the authors discuss the importance of the role of the state in the development of the economy. They argue that the state should play a leading role in the development of the economy, particularly in the case of developing countries. This is because the state has the power to mobilize resources and to coordinate the activities of different sectors of the economy. In the second part of the paper, the authors discuss the role of the state in the development of the infrastructure. They argue that the state should invest in the development of the infrastructure, particularly in the case of developing countries. This is because the infrastructure is a key factor in the development of the economy, and the state has the power to invest in it.

In the third part of the paper, the authors discuss the role of the state in the development of the human resources. They argue that the state should invest in the development of the human resources, particularly in the case of developing countries. This is because the human resources are a key factor in the development of the economy, and the state has the power to invest in them. In the fourth part of the paper, the authors discuss the role of the state in the development of the environment. They argue that the state should invest in the development of the environment, particularly in the case of developing countries. This is because the environment is a key factor in the development of the economy, and the state has the power to invest in it.

In the fifth part of the paper, the authors discuss the role of the state in the development of the social services. They argue that the state should invest in the development of the social services, particularly in the case of developing countries. This is because the social services are a key factor in the development of the economy, and the state has the power to invest in them. In the sixth part of the paper, the authors discuss the role of the state in the development of the culture. They argue that the state should invest in the development of the culture, particularly in the case of developing countries. This is because the culture is a key factor in the development of the economy, and the state has the power to invest in it.

In the seventh part of the paper, the authors discuss the role of the state in the development of the science and technology. They argue that the state should invest in the development of the science and technology, particularly in the case of developing countries. This is because the science and technology are a key factor in the development of the economy, and the state has the power to invest in them. In the eighth part of the paper, the authors discuss the role of the state in the development of the health care. They argue that the state should invest in the development of the health care, particularly in the case of developing countries. This is because the health care is a key factor in the development of the economy, and the state has the power to invest in it.

In the ninth part of the paper, the authors discuss the role of the state in the development of the education. They argue that the state should invest in the development of the education, particularly in the case of developing countries. This is because the education is a key factor in the development of the economy, and the state has the power to invest in it. In the tenth part of the paper, the authors discuss the role of the state in the development of the housing. They argue that the state should invest in the development of the housing, particularly in the case of developing countries. This is because the housing is a key factor in the development of the economy, and the state has the power to invest in it.

In the eleventh part of the paper, the authors discuss the role of the state in the development of the transportation. They argue that the state should invest in the development of the transportation, particularly in the case of developing countries. This is because the transportation is a key factor in the development of the economy, and the state has the power to invest in it. In the twelfth part of the paper, the authors discuss the role of the state in the development of the communication. They argue that the state should invest in the development of the communication, particularly in the case of developing countries. This is because the communication is a key factor in the development of the economy, and the state has the power to invest in it.

In the thirteenth part of the paper, the authors discuss the role of the state in the development of the energy. They argue that the state should invest in the development of the energy, particularly in the case of developing countries. This is because the energy is a key factor in the development of the economy, and the state has the power to invest in it. In the fourteenth part of the paper, the authors discuss the role of the state in the development of the water supply. They argue that the state should invest in the development of the water supply, particularly in the case of developing countries. This is because the water supply is a key factor in the development of the economy, and the state has the power to invest in it.

In the fifteenth part of the paper, the authors discuss the role of the state in the development of the waste management. They argue that the state should invest in the development of the waste management, particularly in the case of developing countries. This is because the waste management is a key factor in the development of the economy, and the state has the power to invest in it. In the sixteenth part of the paper, the authors discuss the role of the state in the development of the urban planning. They argue that the state should invest in the development of the urban planning, particularly in the case of developing countries. This is because the urban planning is a key factor in the development of the economy, and the state has the power to invest in it.

GOVERNMENT AND NON-PROFIT ORGANISATION INITIATIVES

1. **Coronavirus Response Management Platform (CRMP):** The state government in collaboration with Deloitte, deployed an Artificial Intelligence (AI) based questionnaire to evaluate the condition of Nizamuddin returnees to Odisha while they were quarantined in their homes. The AI questionnaire was used extensively to identify and geo-locate high-risk groups to provide them with customized treatment and routine follow-ups. This module is a cloud-based population analytics platform utilizing 1500 social determinants of health to identify populations with a higher chance of facing impediments to self-quarantine to direct them to nearby services.
2. **Operational Telemedicine Service:** Using Interactive Voice Response (IVR) tool, the Odisha government provided a free-of-charge telemedicine helpline service for patient consultation and to disseminate information to access various COVID-19 resources. Deployment of this service employed 300 medical professionals who alleviated public apprehension related to coronavirus.

GOVERNMENT AND NON-PROFIT ORGANISATION INITIATIVES

Sanket: It is a compact, affordable and portable ECG device designed for remote locations. The state government and Tata Trust will make this device available in three districts covering all 39 PHCs to provide timely cardiac care through this initiative.²³

GOVERNMENT INVESTMENTS IN HEALTH (2021-22 BE)

HIGHLIGHTS

- INR 120 M and 44 M were donated to about 84,000 construction workers and Above Poverty Line (APL) families through the COVID-19 Emergency Relief Scheme.
- Construction of Trauma care facilities at District Hospitals in Dhalai, Dharmanagar, Udaipur, Tepania, Santribazar along with 100 bedded Sub-Divisional Hospital at Sabroom is sanctioned
- The upgrade of CHCs at Kumarghat, Panisagar and Karbook into 50-bed Sub-Divisional Hospitals are in progress
- PHCs in West Tripura, South Tripura and Dhalai districts have been upgraded to 10-bedded Hospitals
- Medical college seats have been increased for MBBS (25), PG (16) along with nursing seats (265) in BSc, MSc courses

the 1990s, the number of people in the UK who are employed in the public sector has increased from 10.5 million to 12.5 million, and the number of people in the public sector who are employed in health care has increased from 1.5 million to 2.5 million (Department of Health 2000).

There are a number of reasons for this increase. One of the main reasons is the increasing demand for health care services. The population of the UK is increasing, and the number of people who are aged 65 and over is increasing rapidly. This has led to an increase in the number of people who are in need of health care services, and this has led to an increase in the number of people who are employed in the public sector.

Another reason for the increase is the increasing demand for health care services from the private sector. The private sector has been expanding rapidly in the UK, and this has led to an increase in the number of people who are employed in the private sector. This has led to an increase in the number of people who are employed in the public sector, as the public sector has had to take on more people to meet the demand for health care services.

A third reason for the increase is the increasing demand for health care services from the voluntary sector. The voluntary sector has been expanding rapidly in the UK, and this has led to an increase in the number of people who are employed in the voluntary sector. This has led to an increase in the number of people who are employed in the public sector, as the public sector has had to take on more people to meet the demand for health care services.

There are a number of challenges that the public sector faces in meeting the demand for health care services. One of the main challenges is the increasing demand for health care services, which has led to a shortage of health care workers. This has led to an increase in the number of people who are employed in the public sector, as the public sector has had to take on more people to meet the demand for health care services.

Another challenge is the increasing demand for health care services from the private sector. The private sector has been expanding rapidly in the UK, and this has led to an increase in the number of people who are employed in the private sector. This has led to an increase in the number of people who are employed in the public sector, as the public sector has had to take on more people to meet the demand for health care services.

A third challenge is the increasing demand for health care services from the voluntary sector. The voluntary sector has been expanding rapidly in the UK, and this has led to an increase in the number of people who are employed in the voluntary sector. This has led to an increase in the number of people who are employed in the public sector, as the public sector has had to take on more people to meet the demand for health care services.

There are a number of ways in which the public sector can meet the demand for health care services. One of the main ways is to increase the number of people who are employed in the public sector. This can be done by recruiting more people to the public sector, and by providing training and development opportunities for existing staff. This will help to ensure that the public sector has enough people to meet the demand for health care services.

Another way is to increase the demand for health care services from the private sector. The private sector can be encouraged to expand its services, and this will help to reduce the demand for health care services from the public sector. This will help to reduce the number of people who are employed in the public sector, and this will help to reduce the cost of health care services.

GOVERNMENT AND NON-PROFIT ORGANISATION INITIATIVES

1. Tools developed by the State Disaster Management Authority (SDMA):
 - a. Tracking individuals under home quarantine: Maintaining a database of people under home quarantine with their location and mobile number details. SDMA's tool alerts the district authorities if any person in-home quarantine crosses their geo-fences.
 - b. Tracking the travel history of individuals by using mobile tower signals to determine what places a person travelled to in the past. These details are then used by authorities to assess the possible spread of the infection in different locations of a region.
2. TruNAT testing machines, previously used for detecting TB, were also used for novel coronavirus to expand the testing capacity.
3. YSR Telemedicine facility launched by the CM for the public, which could be accessed by dialling 14410.
4. COVID-19 Dashboard was developed to keep track of vacant and total hospital beds in the state and other vital numbers.

GOVERNMENT AND NON-PROFIT ORGANISATION INITIATIVES

1. **Quarantine Monitor^{ix}**: App developed by the Tamil Nadu State Government's e-Governance Agency to track the movement of COVID-19 suspects under home quarantine. It alerts the monitoring authorities if the suspect moves beyond the designated fences and tracks symptoms of people quarantined at home.
2. Tamil Nadu e-Governance Agency created an Interactive Voice Response System (IVRS)^{xx} version of the Aarogya Setu application to analyze an individual's health condition based on their response to the IVRS. Available in Tamil, it can function without an internet connection.
3. **Tanjore Air Barrier Technique in Madurai**: Meenakshi Mission Hospital and Research Centre in Madurai used this technique for delivering compressed medical-grade air to health personnel in operation theatres through a hood and Bluetooth stethoscope. The technology leverages AI and Robotics for detecting symptoms in visitors (through smart infrared AI helmets for checking temperature, innovative fever clinics, and smart thermal surveillance cameras), sterilizing facilities as well as treating patients without the need for contact."
4. **CoBuddy^{xxi}**: It is an android-based geofencing mobile app used by Police authorities in the Tiruvallur district. It works by using face verification as an additional layer of protection. For this, random messages are sent to the quarantined user to upload their photograph and verify their current location throughout the day.

GOVERNMENT AND NON-PROFIT ORGANISATION INITIATIVES

1. **T-COVID'19/HIMAT Application^{xxxv}**: Built jointly by Cisco, AWS, and Quantella and promoted by the Departments of health and information technology, it provides monitoring and telemedicine services to patients. It also enables patients to carry out a self-assessment and helps them connect with doctors to clear doubts and misconceptions.
2. **COVIHOME^{xxxvi}**: Researchers at IIT-Hyderabad developed an AI-powered affordable COVID-19 test that can be performed at home. The kit can produce results within 30 mins for both symptomatic and asymptomatic patients, and it does not require an expert or an RT-PCR. A report by CSIR-Centre for Cellular & Molecular Biology (CCMB) confirmed the kit's efficiency was 94.2%, sensitivity 91.3%, and specificity 98.2%.
3. Collaboration with Hyderabad-based start-up Vera Healthcare^{xxxvii} for monitoring the containment zones by using a traveller tracking system to record travel history, symptoms, and contacts of passengers on the railway. The app enables live surveillance, monitoring, tracking, reporting, and essential bulletins related to this deadly disease. It uses geotagging and GPS tracking technology to track people who are quarantined at home.
4. **Smart ventilator**: Developed by Leven Medical, a start-up under the state government's initiative – Hyderabad Security Cluster. It uses AI and ML^{xxxviii} to allow doctors to remotely manage a patient's health by collecting vitals and data. It also helps to trace contacts of a patient to create a repository for governments and epidemiologists.
5. **'Medicines from the Sky' Project^{xxxix}**: Pilot project for delivery of medical supplies to remote areas by Flipkart and the government of Telangana. The idea is to develop and execute drone deliveries of medical supplies to remote locations for now and the future.

GOVERNMENT INVESTMENTS IN HEALTH (2021-22 BE)

HIGHLIGHTS

- INR 75,000 M will be spent over four years to upgrade health institutions under the Public Health Department.
- INR 8,000 M out of the designated INR 50,000 M will be released in 2021-22 to improve health services and infrastructure in municipal councils and Nagar Panchayats.
- In a public-private-partnership mode, new medical colleges have been authorised in Sindhudurg, Osmanabad, Nashik, Raigad, Satara, Amravati and Parbhani districts.
- “Post Covid Counselling and Treatment Centres” will be started in every district hospital and government medical college to assist in long COVID-19 and post COVID-19 symptoms, including psychological.

Overview

India accounts for one of every 10 of the cumulative confirmed COVID-19 infections across the world; more than one-third of Asia's.¹ The recorded deaths are nearly 9 percent of the world's total. It has the second highest number of infections in the world, with the states of Maharashtra, Kerala, and Karnataka reporting the most.² At the time of writing, scientists have identified five new "variants of concern"—i.e., alpha, beta, gamma, delta, and omicron—or mutations of the earliest SARS-CoV-2 that have higher transmissibility or virulence, and are challenging the effectiveness of public health and social measures currently in place.³

FIGURE 4: NUMBER OF COVID-19 ACTIVE CASES AND DEATHS IN INDIA (AS OF 1 MARCH 2022)

COVID-19 INDICATORS: CONFIRMED CASES (AS OF 30 NOVEMBER 2021)
FIGURE 5: CUMULATIVE CONFIRMED COVID-19 CASES ACROSS INDIA

Source: COVID19bharat.org

The treemap graphs (Figures 5 and 6) show the COVID-19 cases across the country's states. The bigger the size of the state compartment, the higher is its contribution to the overall number. In absolute terms, Maharashtra, Kerala, Karnataka, and Tamil Nadu have recorded the highest numbers of cases. With respect to population, the caseload burden was remarkably heavier for smaller states and for UTs, such as Lakshadweep, Goa, Mizoram; Kerala, a big state, is an exception.

FIGURE 6: CONFIRMED COVID-19 CASES ACROSS INDIA PER 100,000 POPULATION

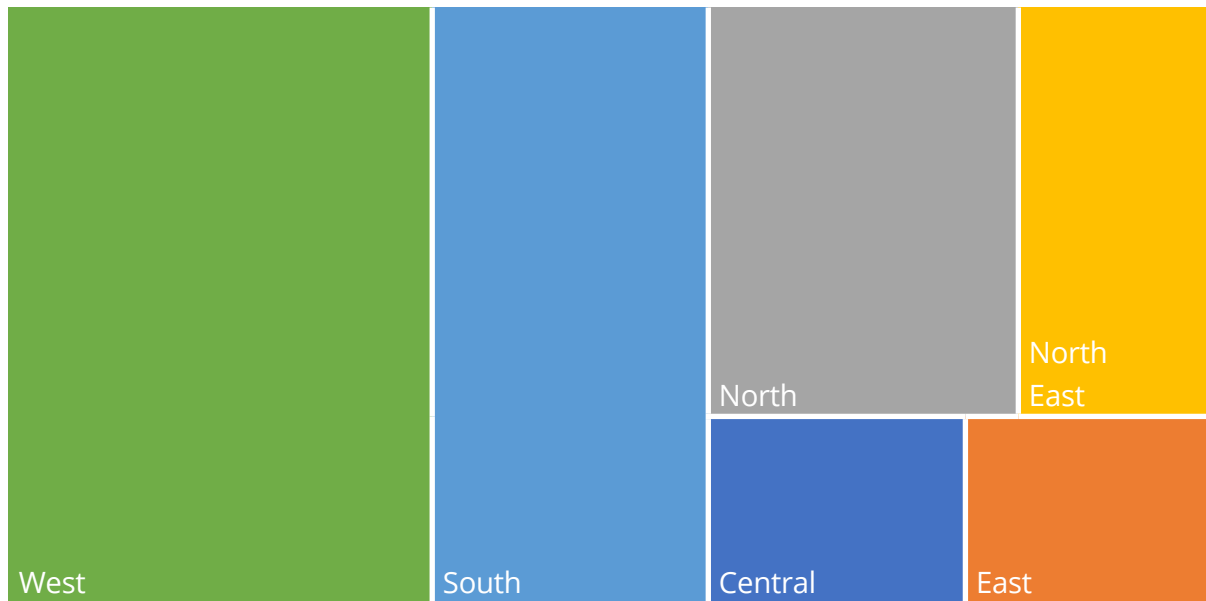

Source: COVID19bharat.org

DEATHS (AS OF 15 DECEMBER 2021)
FIGURE 7: CUMULATIVE CONFIRMED COVID-19 DEATHS ACROSS INDIA

Source: COVID19bharat.org

Following the same trend as for the cases, the cumulative COVID-19 deaths burden (see Figures 7 and 8) is highest for Maharashtra, followed by Kerala, Karnataka, and Tamil Nadu. The deaths per 100,000 population were significantly higher for Kerala, Maharashtra, Delhi, Goa, and Puducherry.

FIGURE 8: CONFIRMED COVID-19 DEATHS ACROSS INDIA PER 100,000 POPULATION

Source: COVID19bharat.org

THE FOLLOWING TRENDS are seen in the state profiles:

- i. The age-wise demographics shows that the top three states with the highest estimated proportion of population 60 years and older, are in Kerala, Tamil Nadu, and Himachal Pradesh. Meanwhile, the highest percentage of under-18s is concentrated in the north-eastern region, with Meghalaya, Arunachal Pradesh, and Nagaland leading. With children being the biggest non-immunised demographic group across all populations, India faces the massive task of providing them with safe and effective vaccines against COVID-19.

FIGURE 9: DEMOGRAPHICS ACROSS INDIA'S STATES AND UTs, BY AGE

Source: Report of the Technical Group on Population Projections (2019) for larger states and computed by authors for smaller states

- ii. Monthly per-capita out-of-pocket expenditure on health was highest in Jammu and Kashmir and Ladakh (18.6 percent each), followed by Arunachal Pradesh and Kerala (17 percent each). While this indicator reflects poorly on government support for public health, and lack of financial coverage, it can also be interpreted as the population's active healthcare-seeking behaviour.

FIGURE 10: MONTHLY PER CAPITA OUT-OF-POCKET EXPENDITURE ON HEALTH AS A SHARE OF PER CAPITA CONSUMPTION EXPENDITURE ACROSS INDIA

Source: SDG 3 Index (2020)

- iii. Overall, the coverage of the general population with any kind of health insurance or financing scheme was very low at about 40 percent, as per NFHS-5. Among the states, coverage is highest in Rajasthan (87.8 percent), followed by Chhattisgarh (71.4 percent) and Andhra Pradesh (70.2 percent).

FIGURE 11: HEALTH INSURANCE OR FINANCING SCHEME COVERAGE ACROSS INDIA

- iv. Government support in the form of per capita revenue expenditure in Medical and Public Health and Family Welfare was highest in the smaller states of Sikkim (INR 743.39 per 10,000 population), Goa (INR 778.82), and Arunachal Pradesh (INR 617.83). These are clear outliers from the overall trend across states and UTs in the country, with average revenue expenditure on health at INR 271.26 in 2020-21 and INR 291.43 in 2021-22 per 10,000 population.

FIGURE 12: PER CAPITA REVENUE EXPENDITURE ON HEALTH ACROSS INDIA

Source: State Finances: Study of Budgets (2020), Reserve Bank of India

- v. Human resources in Health: India has 36.3 physicians, nurses, and midwives (taken together) and 10.5 pharmacists per 10,000 population. Kerala's number (115 for physicians, nurses and midwives) is significantly higher than the country's average. Further, four of the top five states in the physicians, nurses and midwives category are from the southern region.

Meanwhile, the number of registered pharmacists with respect to population is higher in the smaller states and in the UTs. Chandigarh is an outlier, with 33 registered pharmacists per 10,000 people.

- vi. Medical infrastructure on the population level: COVID-19 Testing capacities are clearly deficit. Only smaller states and UTs like Ladakh, Lakshadweep, and Goa have at least one testing laboratory or sample collection centres per 10,000 population. Smaller states and UTs such as Arunachal Pradesh, Ladakh, and Andaman & Nicobar Islands are some better-performing regions.
- vii. Technological infrastructure: Less than 10 states regularly report gender- and age-wise segregated data. While most states and UTs make available historical outcomes-related data on their dedicated COVID-19 portals, real-time updates on availability of hospital beds, ventilators, and others—which contribute critically to these outcomes—are seldom provided.

A Health Systems Resilience Index for India's States and Union Territories

Structure and Sub-Indices

The prolonged COVID-19 pandemic has served as a “stress test” for India’s health systems. Did those systems pass the stress test, or did they fail? More importantly, have those systems been strengthened since, in order for them to become more resilient in the event of subsequent waves of COVID-19, or else another health crisis of similar magnitude?

This section offers answers to these questions in the form of a Health Systems Resilience Index.^{1,2} The index will illustrate both, the performance of each of India’s 28 states and eight UTs, as they responded to the past waves of the COVID-19 pandemic, and their resilience against future crises. The index uses a nested structure. It comprises five sub-indices that score the Indian states’ and UTs’ performance across various parameters relating to general health outcomes, medical and technology infrastructure, institutional support, and COVID-19-related health outcomes. The five sub-indices cut across five domains of healthcare infrastructure and impact assessment, particularly relevant for the COVID-19 pandemic. Four of these sub-indices—General Health Profile, Medical Infrastructure, Technology Infrastructure, and Institutional Support—account for the size of the resource base of the states and UTs. Meanwhile, the COVID-19-related Health Outcomes sub-index accounts for the efficiency of resource mobilisation during the preceding two waves of infections, measured using proxies of relevant input and output variables.

FIGURE 14: STRUCTURE OF THE HEALTH SYSTEMS RESILIENCE INDEX

Source: Authors' own

Sub-Indices: An Overview

General health profile: This sub-index provides an aggregate picture of the general health of the population in that state or UT as a baseline case prior to the onset of the pandemic in early 2020. It captures the overall levels of prevailing healthcare services and the associated financial stress on households. It is relevant to study this baseline effect across states and UTs for various reasons. First, poor overall health quality is expected to affect not only the spread of the pandemic but also its outcomes. Second, until very recently, vaccines were available only for the 18+ years age group, which left a sizeable portion of the Indian population unattended during the 2020 and 2021 COVID-19 waves. Lastly, a considerable fraction of the country's health services are shouldered by the private sector; it is necessary to account for the plausible financial stress on individuals and households.

Medical infrastructure: The availability of adequate medical infrastructure becomes even more critical amidst a prolonged pandemic such as that of COVID-19. This sub-index measures the pre-pandemic state of health infrastructure across the states and UTs, as well as the burden that the pandemic has placed on these systems and infrastructure, and how quickly the State and the Central governments managed to respond.

Technology infrastructure: This component index provides a measure for connectivity, and the availability of relevant infrastructure in a state or UT. These facilitate the distribution of resources and aid in information dissemination. It also incorporates factors such as data availability, ease of accessibility, and granularity of reported data. Efficiency in data reporting enables the system's functioning and informs decision-making and emergency communication.

Institutional support: This sub-index measures the support provided by the state to the various institutions that comprise the health sector, which in turn provide the financial and structural backbone for the system at the forefront of the pandemic battle. For this sub-index, it is defined by the per capita revenue expenditure in the healthcare sector of the respective state or UT. Furthermore, to measure the degree of response shown by the state or UT, the changes in public expenditure on healthcare over the two years of the pandemic have also been considered and compared to the “business as usual” scenario.

COVID-19-related health outcomes: These parameters help understand the extent of the spread of the pandemic across populations and gauge impacts in terms of health outcomes. The efficiency in mobilising COVID-19 pandemic-induced health infrastructure is measured by using critical indicators such as the time taken by the state or UT to bring down positivity rates or improve vaccination coverage, particularly for the vulnerable elderly, and achieve spatial and gender equity in the inoculation drive. Overall levels of testing and vaccination attained account for the demand for these critical health services among the population. Moreover, testing rates, in conjunction with the number of COVID-19 cases, adjust for under-reporting of numbers by any state or UT.

The composite index consists of both static and dynamic variables to capture changes in responses, and the results of those responses. It therefore emerges as a combination of initial conditions that are reflective of the health preparedness of a sub-national unit, the response mechanism to the pandemic, and the final outcomes. The static variables include General Health Profile, Medical Infrastructure, Technology Infrastructure, and the two revenue expenditure variables under institutional support, and the vaccine doses, tests, deaths, peak daily case load under COVID-19-related health outcomes. Meanwhile, the dynamic variables cover the two related to revenue change under institutional support, and the time taken between the highest peak of daily cases to its 20 percent, time taken between peak positivity rate to fall below 5 percent, days taken to reach benchmark vaccination coverage of 18+ population, and weeks taken to reach benchmark vaccination coverage of 60+ population under COVID-19-related Health Outcomes. (Details on the variables and data sources are given in Table A2 in Appendix 1.)

Results and Analysis

THE HEALTH SYSTEMS RESILIENCE INDEX (HSRI), including its five component indices, has been computed for all of India's 20 large states,³ eight small states, and eight Union Territories, using a two-stage weighted average. For the assignment of weights in the first stage, the authors conducted a Principal Component Analysis (PCA) with 33 component indicators. In the second stage, weights were dictated by informed arbitrariness. Subjectively determined weights were assigned driven by the motivation to simultaneously capture variations in capacities and performance of health systems across regions (See Annexure II for detailed data sources and methodology). The following sections will consider the index scores computed across all states and UTs and identify broad trends in terms of performance during the 2020 and 2021 waves of the COVID-19 pandemic. The analysis also uses the computed scores to classify the states and UTs into six degrees of resilience from Low to High. This enables the identification of clustering patterns and, accordingly, traces the factors that have led to such rankings.⁴

a. Sub-Index 1: General Health Profile

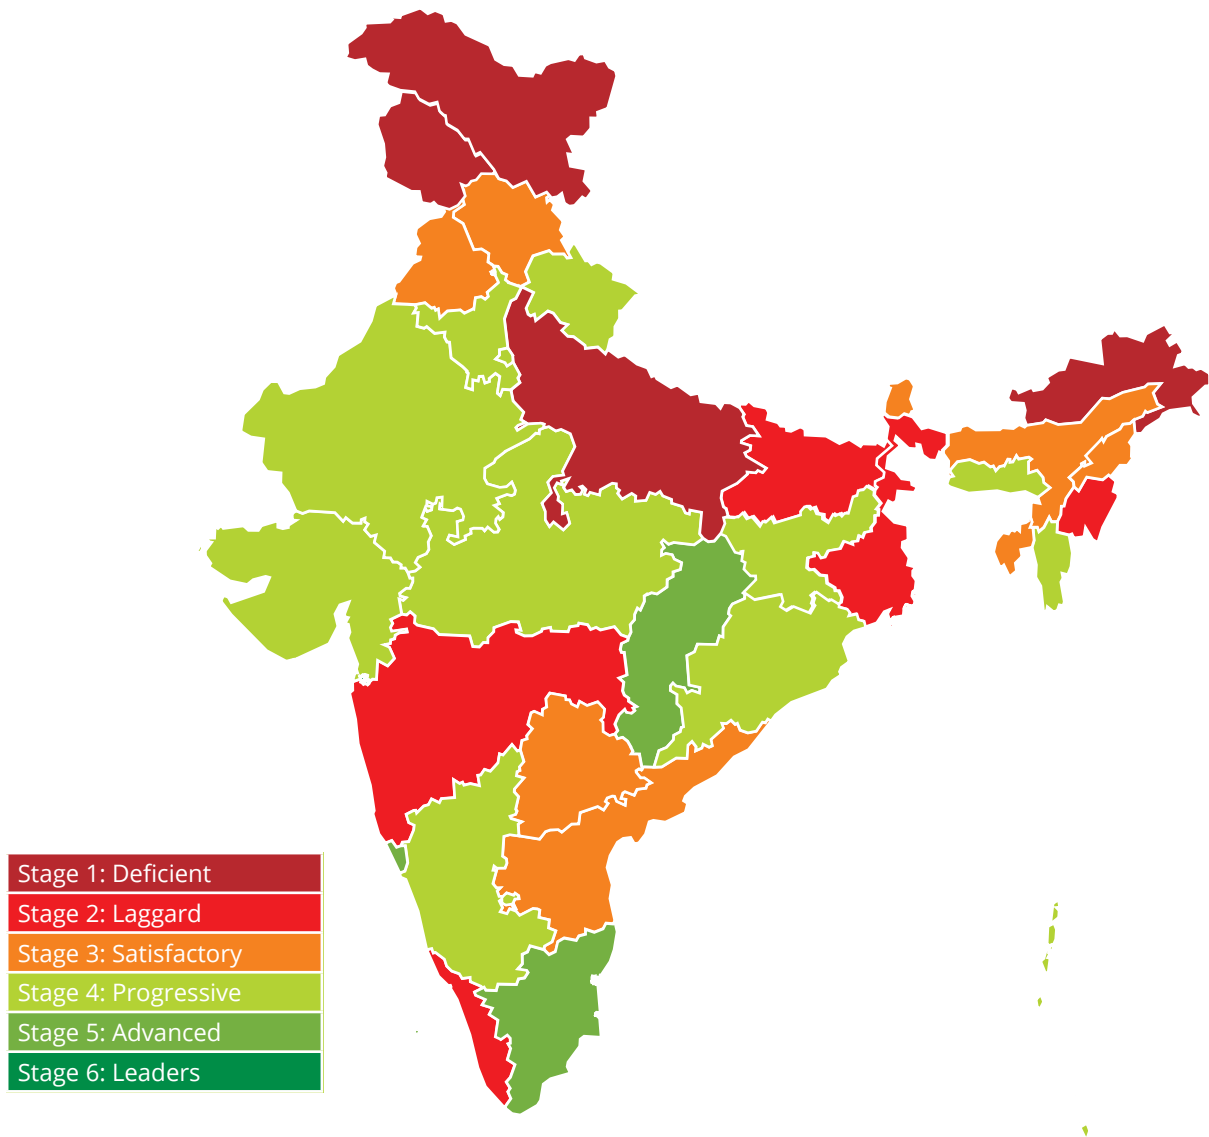

Table 1 shows the computed scores and rankings in the General Health Profile Sub-index for India's 20 large states, eight smaller states, and eight UTs, with 1 being the maximum score and 0, the minimum.

TABLE 1: GENERAL HEALTH PROFILE INDEX SCORES AND RANKING

Large States		
Tamil Nadu	0.86	1
Chhattisgarh	0.82	2
Rajasthan	0.76	3
Karnataka	0.74	4
Gujarat	0.73	5
Haryana	0.68	6
Odisha	0.68	7
Jharkhand	0.68	8
Uttarakhand	0.68	9
Madhya Pradesh	0.62	10

FIGURE 15: GENERAL HEALTH PROFILE INDEX SCORES OF INDIAN STATES AND UNION TERRITORIES

Among the larger states, Tamil Nadu has the highest score, at 0.86, in terms of general health; of the smaller states, Goa ranks first, with 0.81. Most western and southern states perform relatively well, compared to the rest of India. Kerala and Maharashtra are two regional outliers, having significantly low scores—in Kerala, it is primarily due to catastrophic out-of-pocket expenditure on health, and in Maharashtra, inadequate insurance coverage is mainly to blame. In northern India, all states (except Himachal Pradesh and Punjab) perform considerably well in this domain. Among the eastern and central states, Odisha, Jharkhand and Chhattisgarh perform significantly well. There are no clear regional trends observed among the North-East Region (NER) states. Arunachal Pradesh is at the tail of all the states and UTs, scoring 0.25 in this sub-index. All UTs except the recently formed Ladakh, and Jammu & Kashmir perform well in the “General Health Profile” parameter, with Dadra & Nagar Haveli and Daman & Diu performing best among all states and UTs.

b. Sub-Index 2: Medical Infrastructure

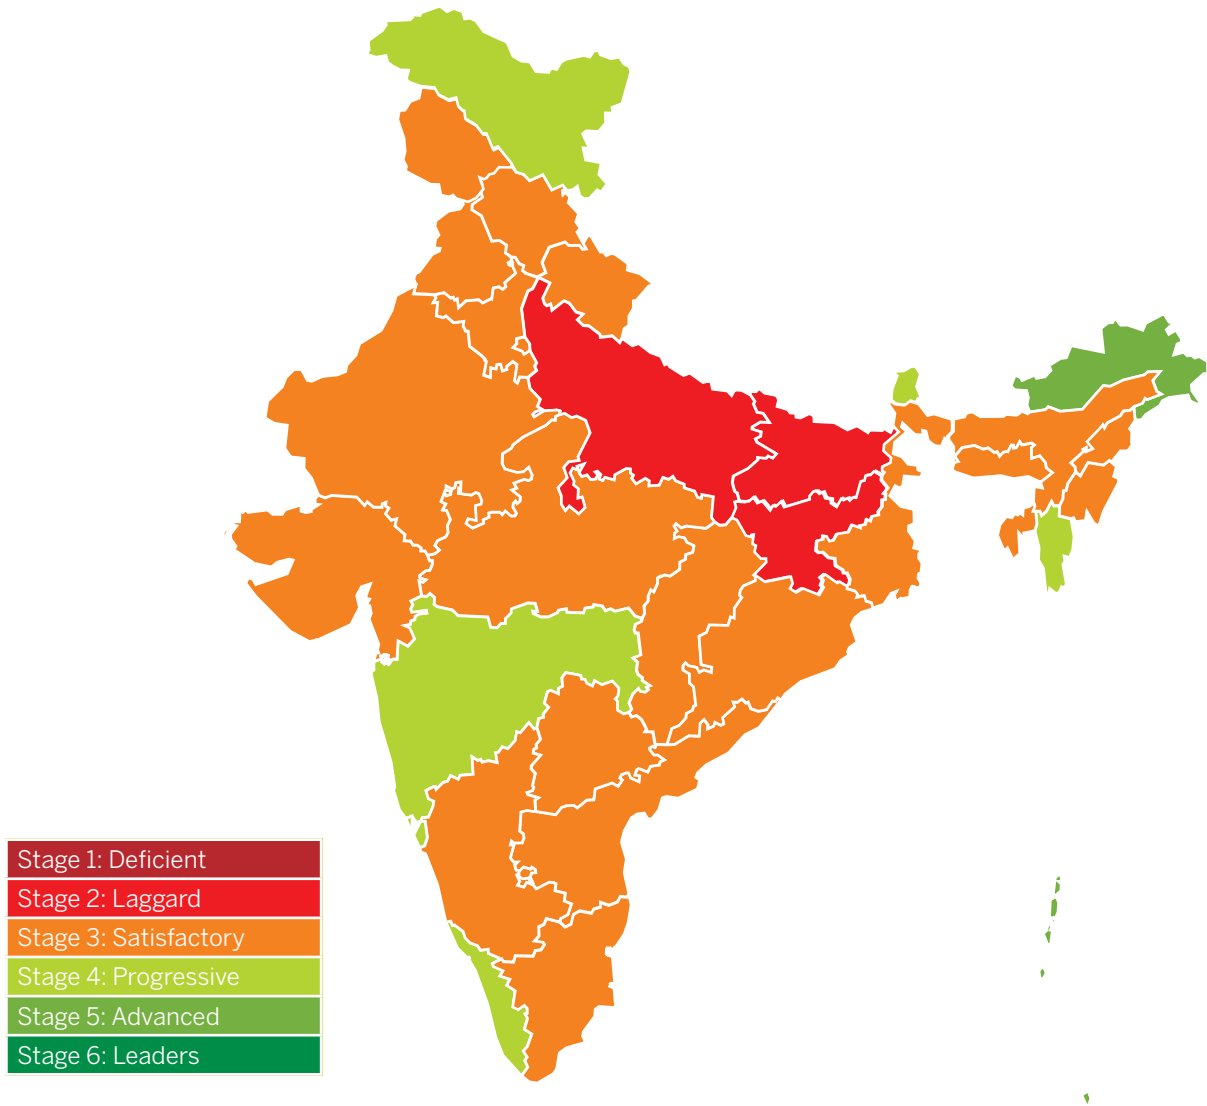

Table 2 shows the computed scores and rankings in the Medical Infrastructure Sub-index for India's 20 large states, eight smaller states, and eight UTs, with 1 being the maximum score and 0, the minimum.

TABLE 2: MEDICAL INFRASTRUCTURE INDEX SCORES AND RANKING

Large States		
Kerala	0.20	1
Maharashtra	0.20	2
Karnataka	0.19	3

Source: Authors' own

FIGURE 16: MEDICAL INFRASTRUCTURE INDEX SCORES FOR INDIAN STATES AND UNION TERRITORIES

In this parameter, Lakshadweep scores the highest overall, i.e., 0.85, among all states and UTs. Arunachal Pradesh is the best performer among smaller states with a score of 0.38. It is clear that the smaller states and UTs have significantly better medical infrastructure than the larger states. Among the larger states, the average level of medical infrastructure is significantly low, with the states in the south, west, and northern regions slightly outdoing the eastern and central states. Kerala ranks the highest among the large states while Bihar, with 0.02, scores the lowest among all states and UTs.

c. Sub-Index 3: Technology Infrastructure

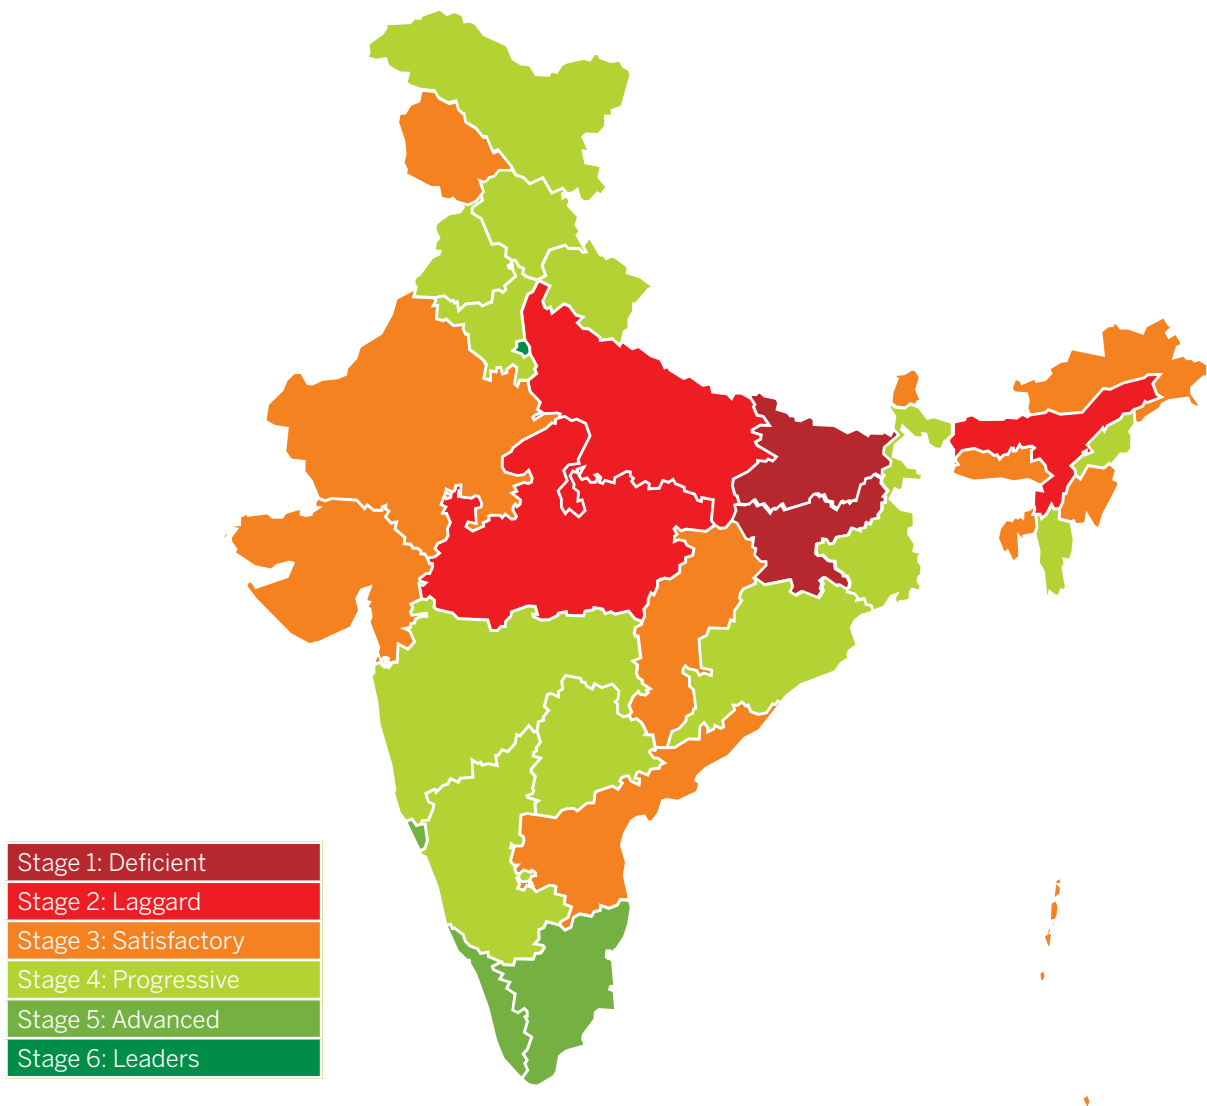

Table 3 shows the computed scores and rankings in the Technology Infrastructure Sub-index for India's 20 large states, eight smaller states, and eight UTs, with 1 being the maximum score and 0, the minimum.

FIGURE 17: TECHNOLOGY INFRASTRUCTURE INDEX SCORES FOR INDIAN STATES AND UNION TERRITORIES

While technological infrastructure and innovations do not directly contribute to health outcomes, they can enhance the working efficiency of a system. A laggard performance in this domain can severely impact the overall resilience of a state or UT, despite adequate responses in other domains.

Delhi performs exceedingly well in this sub-index, scoring 0.83. Indeed, most northern states except Rajasthan, most southern states except Andhra Pradesh, and most western states except Gujarat, wielded technology effectively in their pandemic response in 2020 and 2021. Larger states in the central and eastern regions have lagged considerably in this domain. Notably, Odisha and West Bengal have outperformed the other eastern states. Among the smaller states, Goa scores the highest in this sub-index, at 0.55. Five of the eight small states in the NER had less remarkable tech responses. Unlike in the other parameters, the UTs (except Delhi) score relatively lower in this sub-index.

d. Sub-Index 4: Institutional Support

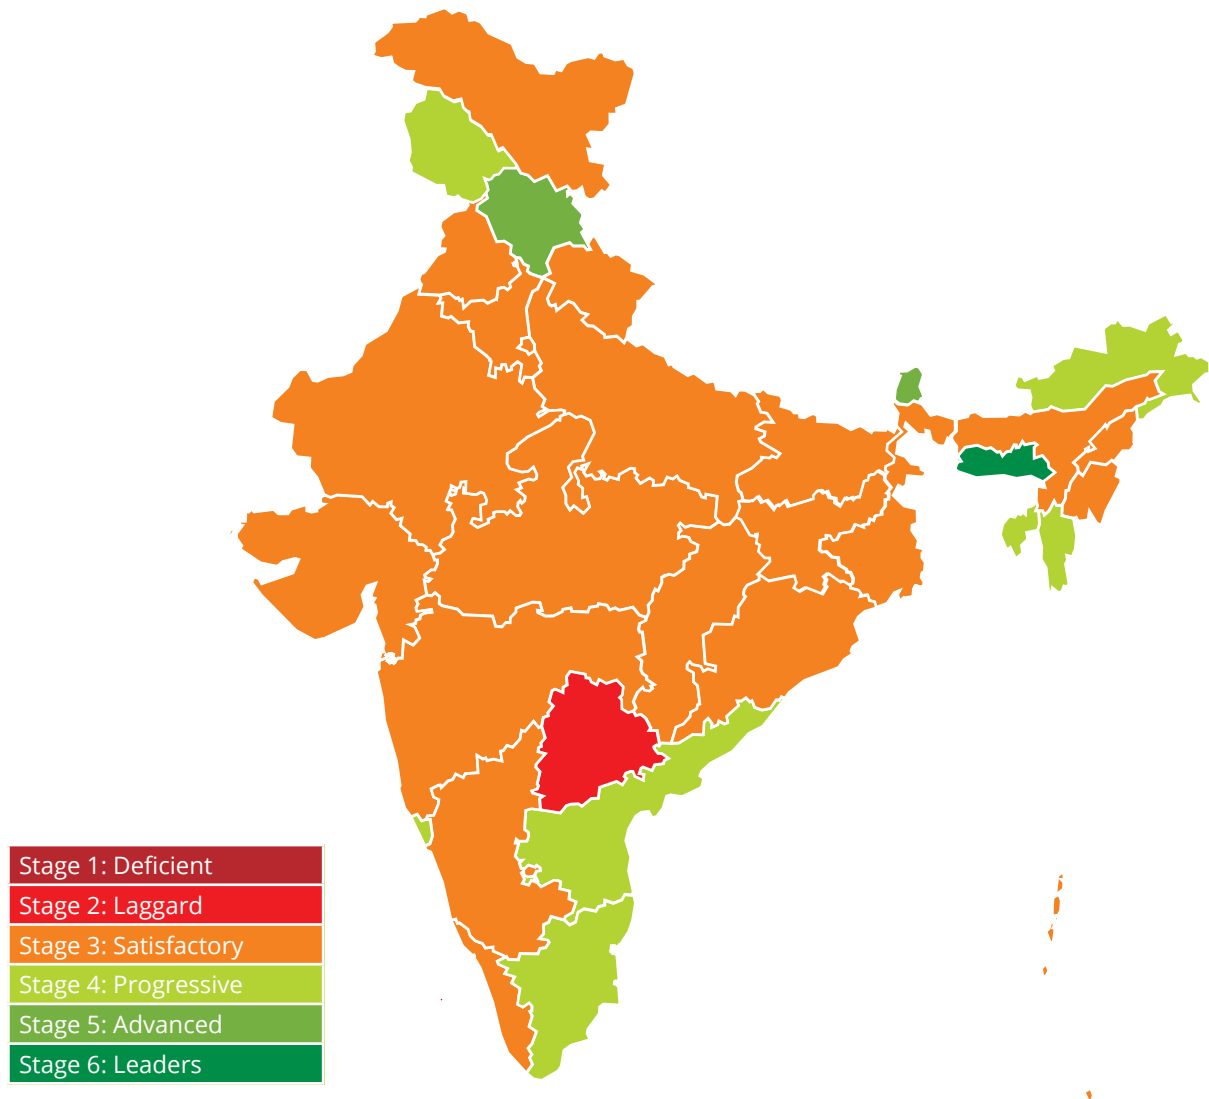

Table 4 shows the computed scores and rankings in the Institutional Support Sub-index for India's 20 large states, eight smaller states, and eight UTs, with 1 being the maximum score and 0, the minimum.

TABLE 4: INSTITUTIONAL SUPPORT INDEX SCORES AND RANKING

Large States		
Himachal Pradesh	0.34	1
Andhra Pradesh	0.29	2

Lakshadweep	0.21	8

Source: Authors' own

FIGURE 18: INSTITUTIONAL SUPPORT INDEX SCORES FOR INDIAN STATES AND UNION TERRITORIES

Meghalaya has done exceedingly well in terms of public provisioning of healthcare over the first two waves of the pandemic, scoring 0.77 in this sub-index. Goa and other smaller states in the NER, as well as the UTs have performed better in this domain, on average, than the larger states, with their sub-index scores hovering between 0.37 and 0.20. Among the larger states, Himachal Pradesh in the north (0.34) and Andhra Pradesh in the south (0.29) have done relatively better in providing institutional support. In this case, the large size of these states, scaled in terms of population, could have had a significant role in straining institutional efforts, thereby reducing the overall preparedness of the general population in these states. Telangana scores the lowest, at 0.11, among all states and UTs taken together.

e. Sub-Index 5: COVID-19-related Health Outcomes

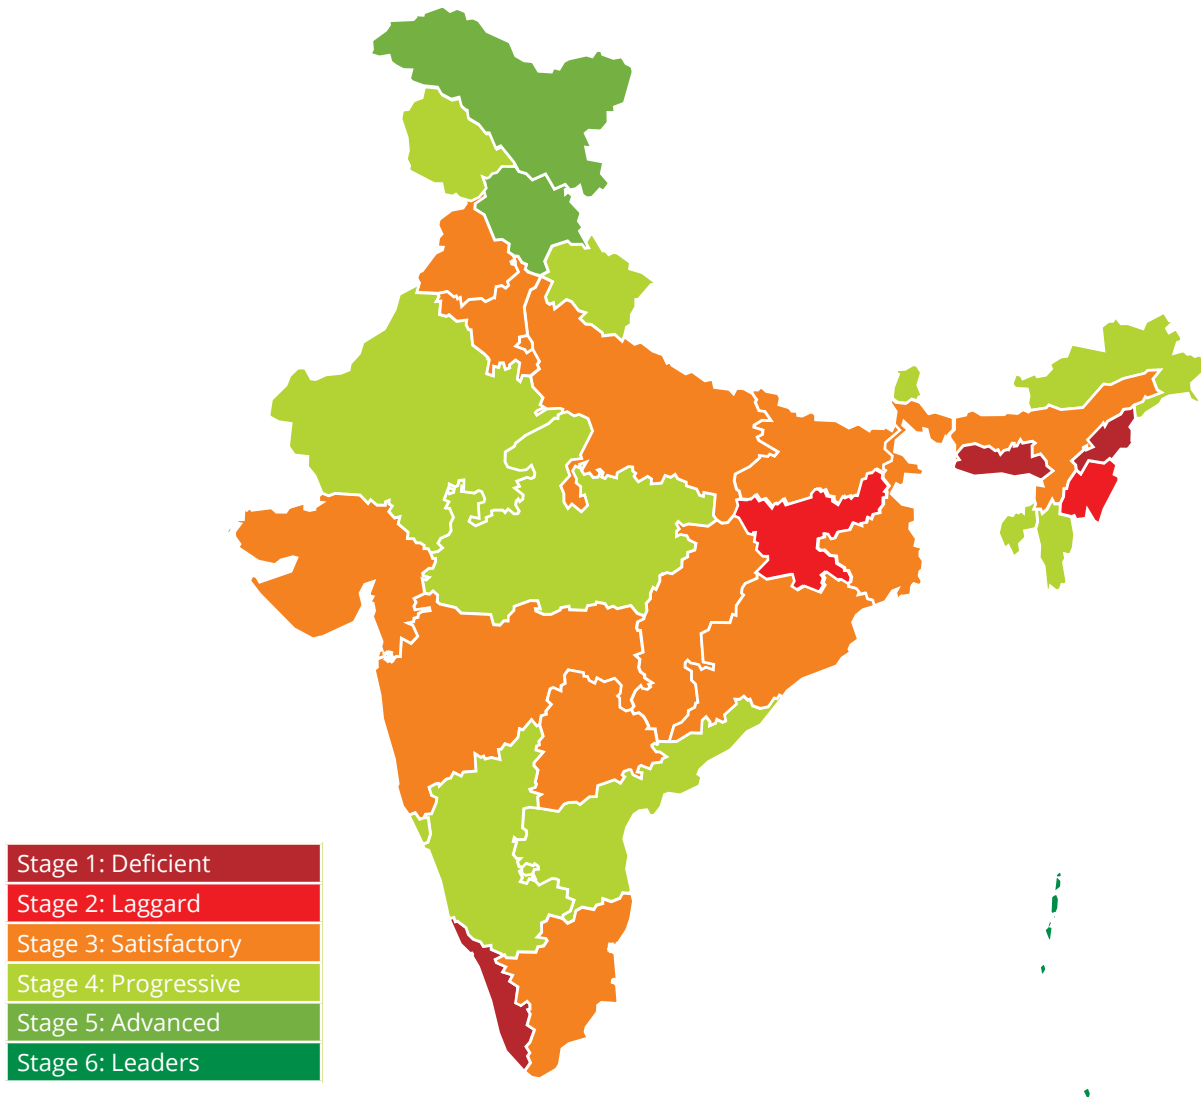

Table 5 shows the computed scores and rankings in the COVID-19-related Health Outcomes Sub-index for India's 20 large states, eight smaller states, and eight UTs, with 1 being the maximum score and 0, the minimum.

TABLE 5: COVID-19-RELATED HEALTH OUTCOMES INDEX SCORES AND RANKING

FIGURE 19: COVID-19-RELATED HEALTH OUTCOMES INDEX SCORES ACROSS INDIAN STATES AND UNION TERRITORIES

Among all states and UTs, Lakshadweep and Andaman & Nicobar Islands, with a score of 0.87 and 0.84, respectively, were most effective in the management of health outcomes during the first two waves of the COVID-19 pandemic. Himachal Pradesh, with a score of 0.77, was the best performer among the larger states, closely followed by the smaller states of Goa, in the west, and Tripura in the north-east. Among the southern states, Kerala scores low, owing primarily to high death rates and low levels of efficiency in resource mobilisation despite a considerably large resource base of supporting infrastructure. Some smaller states in the north-eastern region, such as Manipur, Meghalaya, and Nagaland, score significantly lower compared to their neighbours. Among the UTs, Delhi has lagged behind in effective management of the crisis, scoring the lowest (0.52) in this sub index. While this provides

a broader picture of the relative performance of states and UTs in this domain, a closer inspection of the component indicators may indicate significant under-reporting of cases and deaths in some regions—which in turn may have affected the overall rankings of the states and UTs.

Overall Health Systems Resilience Index

TABLE 6 SHOWS the computed scores and rankings in the final Health Systems Resilience Index for India's 20 large states, eight smaller states, and eight UTs, with 1 being the maximum score and 0, the minimum.

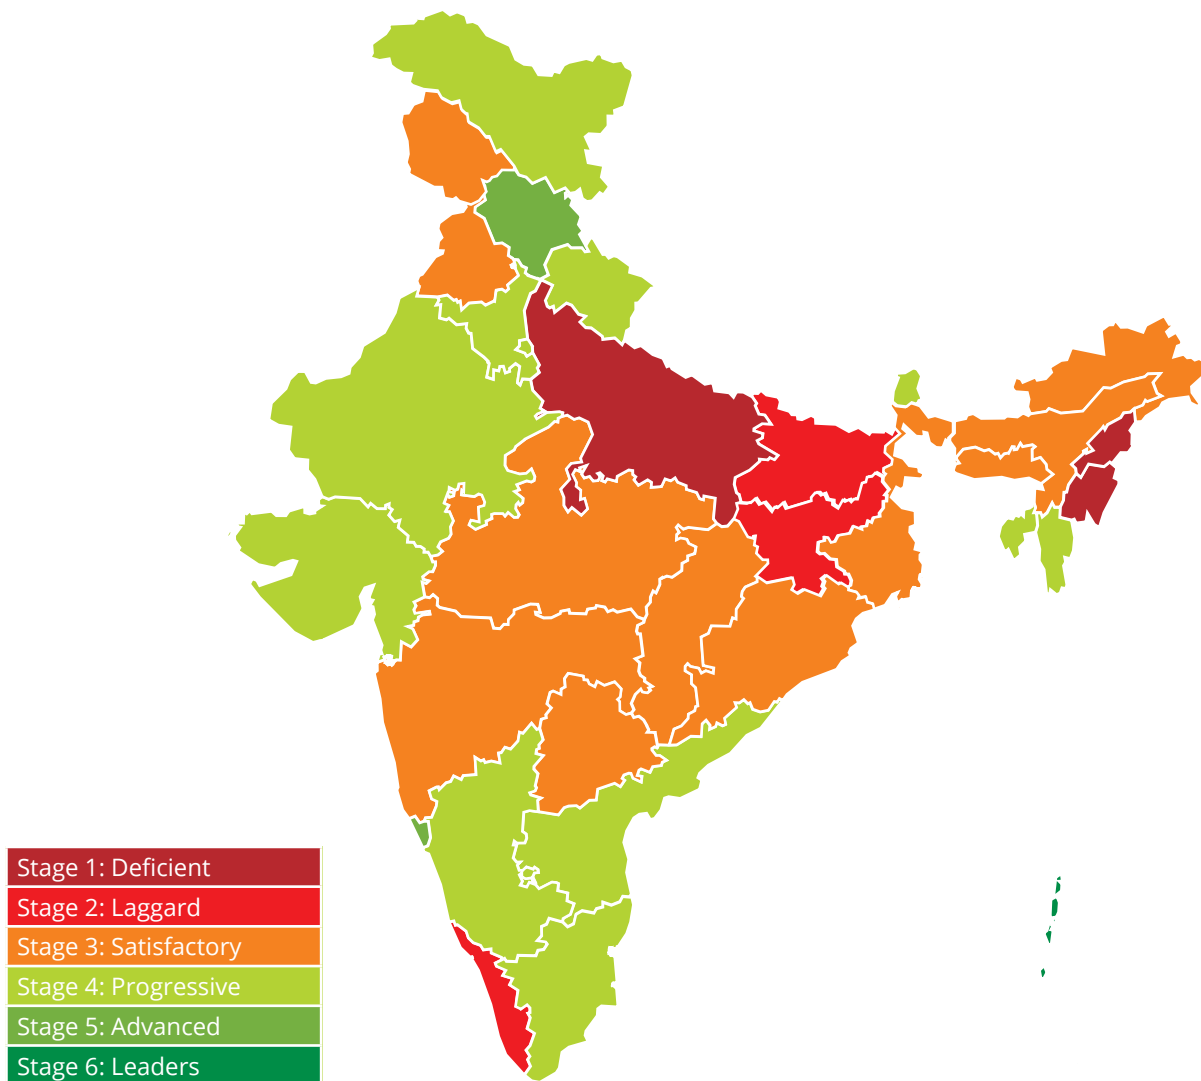

TABLE 6: HEALTH SYSTEMS RESILIENCE INDEX SCORES AND RANKING

Source: Authors' own

FIGURE 20: HEALTH SYSTEMS RESILIENCE INDEX SCORES FOR INDIAN STATES AND UNION TERRITORIES

Lakshadweep and Andaman and Nicobar Islands, among the UTs, have more resilient health systems in place, scoring 0.70 and 0.61 in the composite index, respectively. Among the smaller states, the best performer is Goa (0.59) and of the larger states, Himachal Pradesh (0.58) ranks first. All other UTs are 'satisfactory' or 'progressive' in the measure of resilience of their health systems, with their index scores hovering between 0.56 to 0.47. Most states in the west (except Maharashtra) and most states in the south (except Kerala) have performed better than the eastern and central states.

States like Uttar Pradesh and Bihar, despite exhibiting satisfactory performance in terms of COVID-19-related health outcomes, have a very low resource base that affects the overall resilience of their health systems. Uttar Pradesh ranks last in the overall index, scoring 0.33; Bihar scores 0.36 and is 18th of the 20 larger states. It needs to be noted here that there was rapid response from UP to spur up its resource base during the pandemic, but the state was already operating from a low base that affected its scores. In the northern region, Punjab has the lowest score – exhibiting low health systems resilience – due to its moderate achievements in general health profile and medical infrastructure. The significantly low institutional support also affected its performance in the 2020 and 2021 waves of the pandemic.

States and Union Territories: Crucial Patterns

AS THE SCORES OF all the states and UTs in the Health Resilience Index show, specific regions tend to share certain patterns in how well their health systems responded to the first two waves of the COVID-19 pandemic. For example, most states in the southern and western region have scored significantly well across domains, compared to the eastern and central states. The northern states, on the other hand, have not only established a sound resource base but also translated them into effective pandemic management responses. There also appears to be a clusterisation among the union territories, on one hand, and the states, on the other. Across all domains (except institutional support), union territories score better than the states on an average. In some cases, this trend towards clusterisation is also visible among the larger states, and the smaller ones.

The authors pursued this line of enquiry by comparing the average degree of preparedness between the two sets of clusters: the larger states and the smaller states, as well as the states and the UTs. The instrument used for this part of the analysis is a mean-difference test through the t-statistic. The results for the t-test (that checked for equality between two groups of sample means) are summarised in the Annexure IV (See Table A3 and A4).

The results indicate that there is no statistically significant difference in the average levels of resilience of health systems between the larger states and the smaller ones. However, there is more ease of operation and greater efficiency in the UTs than the states, owing to both, initial conditions and better resource mobilisation by the Centre. The ease with which the Centre launched its operational interventions also helped, in turn influencing overall health governance in the union territories. Efforts in mitigating the impacts of the pandemic have been notably more coherent in the UTs, thereby reducing their overall associated transaction costs and achieving higher levels of efficiency.

There is a case to be made, therefore, for strengthening what analysts call “cooperative federalism”—i.e., better Centre-State collaboration—as the lynchpin of any response mechanism to a crisis. A primary area of cooperation should be finance, which is critical for public provisioning and infrastructure development. India's states are inherently different from one other and are faced with their own specific constraints when it comes to allocating funds for crisis management and disbursing them. Immediate and adequate central funding should be made available as “block grants” for the states to draw upon when necessary. These can effectively relieve some of the constraints and help the states prepare better for another surge in COVID-19 cases or any other health crisis of a similar nature.

Income Levels and Health Systems Resilience

THIS SECTION INVESTIGATES the relationship between the per-capita income levels of the states and UTs, and the overall levels of resilience of their health systems. It is hypothesised that the resilience of the state or UT is positively related to the per-capita income level: that access to resources, or lack of it, directly influences how steadfast a state or UT can be when faced with a massive crisis.⁵ The authors used the correlation coefficient between the per-capita Net State Domestic Product (NSDP) and the Health Systems Resilience Index (HSRI) score to test the validity of this hypothesis. The results of the test are summarised in the Annexure V (see Table A5). The correlation coefficient between per-capita income levels and the HSRI scores is 0.63, indicating a moderately strong positive correlation between the two variables.

Such a correlation is bidirectional: States with more resources are likely going to be better prepared for subsequent bouts with a prolonged COVID-19 pandemic, or any other future shock to the healthcare sector; in turn, as a state or UT is better able to mitigate the fallout of a health crisis, they will likely be able to maintain economic activities and thereby minimise the ramifications on their income.

It is essential to acknowledge, to begin with, the critical role of economic performance in ensuring the availability of adequate resources. Promoting efficiency among the states and UTs, guided by the principles of competitive federalism,⁶ can raise overall income levels and create opportunities for infrastructure development, public provisioning and private sector investments in healthcare services, and consequently, the resilience of the general population. A more targeted econometric analysis will be required to interrogate this bidirectional causality between state/UT incomes and health systems resilience.

-
- ¹ Here, in addition to referring to already established scales of states' performances such as the Bare Necessities Index (Economic Survey 2020, Ministry of Finance) and the SDG India Index (2020), particularly, the progress along SDG 3: Good Health and Well-being, the authors attempt to construct a composite index to assess the preparedness of the Indian states and union territories (UTs) to combat a potential third wave of the Covid-19 pandemic. Indices provide decision-makers with an integrated and informative overview that would be otherwise difficult, if at all possible (Hammond et al. 1995; Neimeijer 2002). This index can provide an objective mode for developing a comprehensive understanding of individual state/UTs' preparedness by bringing together all the parameters under study to arrive at an aggregate score. The objective is to move from multiple indicators to a single metric (Hajkowicz 2006). Besides, indexation can provide a better ground for assessing the relative performance of all the states and union territories and identify existing trends of clusterisations or pockets of performance.
 - ² Keeney and Raiffa (1976) suggest that during certain decision analyses that require making informed choices about multiple objectives, the preferences of the decision-maker are represented numerically through utility function. The weighted SDG index developed by Ghosh et al. (2019) is an example of one such index. In this context, while the Covid-19 Preparedness Index will allow for an overall ranking of the Indian states/UTs' preparedness to combat any following surge in Covid-19 cases, the 5 sub-indices will enable us to track back on factors that are more relevant for better Covid-19 preparedness and identify specific areas which individual states/UTs need to focus on to improve their performance. As such, this index can provide effective learnings for the Indian states/UTs and improve their efficiency towards combating a potential third wave.
 - ³ Based on the computed scores, the Indian states and union territories have been grouped into three categories – large states, small states, and union territories (as classified in Government of India reports) - for ranking purposes to ensure fair comparison between similar entities.

- ⁴ To delineate the scores into corresponding classes, we use the following classification criteria (assuming that the index scores are normally distributed):

Stage 1: Deficient - Index scores $< \mu - 1.5 \sigma$

Stage 2: Laggard - $\mu - 1.5 \sigma < \text{Index scores} < \mu - \sigma$

Stage 3: Satisfactory - $\mu - \sigma < \text{Index scores} < \mu$

Stage 4: Progressive - $\mu < \text{Index scores} < \mu + \sigma$

Stage 5: Advanced - $\mu + \sigma < \text{Index scores} < \mu + 1.5 \sigma$

Stage 6: Leaders - $\mu + 1.5 \sigma < \text{Index scores}$

Where,

μ is the mean of the scores across the states/UTs;

σ is the standard deviation of the scores across the states/UTs.

- ⁶ Competitive federalism is considered as a renewed sense of positive competition among the sub-national economies as a method to enhance efficiency, allow for greater accountability and independence, and induce corrective actions in state policies.

4

Conclusion

Public health surveillance is crucial to tackling infectious diseases; more so during outbreaks, such as the drawn-out COVID-19 pandemic—officially declared in early 2020 and, at the time of writing this report, still continuing to come in waves. The system’s response strategy begins with early detection and containment, and proceeds to tackling the spread at the earliest. In the longer run, the response requires science-informed policy decisions that will enhance capacities and delay the spread of the contagion, in order to allow available infrastructure some space to breathe. Existing systems and resources are then able to combat the pandemic, and the adverse impacts on the population can be minimised.

Despite India's notably successful combat against the pandemic's first wave, the nation faced a massive challenge during the second wave in April 2021, with its poor data-led decisions, limited resources, and the inability to mobilise them in time. For example, absent timely data and with the existing architecture being deficient, there was little knowledge of the true burden of disease, especially NCDs, resulting in a misdirected approach to prioritising vulnerable populations.¹ This is not to say that India’s states and union territories did not exert any effort to expand their infrastructural capacities and nudge public communication for awareness towards pandemic-appropriate behaviour. However, the requirements of India’s massive population overwhelmed its health systems.

To be sure, *better infrastructure* does indicate *better preparedness* for an emergency; yet it is not the sole determinant. ORF's Health Systems Resilience Index tabulated the capacities of the country's states and UTs in health crisis management, using various indicators, among them: medical infrastructure; pre-pandemic morbidities; technological response; and information dissemination. As expansive as these parameters may be, however, they would still not be sufficient to gauge the on-ground realities that determine the degree of success, if any, of that state or UT in tackling the pandemic. Among these are the socio-economic inequities within the population that can determine who gets access to a health commodity even if, theoretically, it is available for all.

While the study has included certain appropriate spatial and gender equity indicators in an attempt to measure access to healthcare among the states' and UTs' most vulnerable populations, these parameters succeed only to a limited extent. Moreover, the available state-level data could not accurately capture the matter of policy stringency for the enforcement of COVID-19 appropriate behaviour.

A particularly important data limitation is the sheer absence of data in the public domain. In fact, several processes and statistics that ought to be duly recorded internally within the system may not be documented in a processable format or made available in open access at all. This undermines the effort to arrive at the truest potential scores. For several indicators, the available information on public services was limited to delivery in government institutions; a large portion of data, which is from the private sector, is missing.

Even with these limitations, however, this entire exercise—of recording each state and union territory's performance in five sets of health and pandemic-related parameters, and thereafter developing a composite index for resilience—still qualifies as a unique contribution to scholarship on the state of India's health systems. Previously acclaimed indices such as the Global Health Security Index and WHO's Joint External Evaluation, both of which assess preparedness, have failed in predicting crisis response; their allotted rankings remarkably did not match COVID-19 outcomes.^{2,3} The scope of traditional indices have restrained them from incorporating unpredictable shocks and measuring non-quantifiable indicators such as social solidarity.

Therefore, one learning that emerged out of this study is that while accurate and timely data is essential, the local, complex socio-political influences are crucial considerations in any attempt to understand a state's public health response. The varied COVID-19 experiences across the states and union

territories make it clear that mere quantifiable metrics, or conventional notions of preparedness limited to technical and physical infrastructure, could still result in an incapacitated response. As Mahajan (2021) observes, these assessments encourage their subjects to build the same infrastructure that are being measured, to begin with.

This report, therefore, is an attempt to emphasise the imperative of having the right physical and technical resources in place to combat a massive crisis such as the COVID-19 pandemic, but not without a localised scheme of crisis response. The novel coronavirus has revealed the failings of health systems and economies across the world, in largely comparable measures. Unless all nations succeed in defeating the pandemic, populations will remain vulnerable; some, more than others. As WHO warns of a future of antigenetically distinct variants of this virus and prolonged recovery periods—clinical care, public health intelligence, community dialogue and counter-measures need to adapt and remain standing.

For a developing country such as India, with a population that is enormous in size and highly heterogeneous, it is important to build adequate infrastructure and develop capacity utilisation that can make a huge impact on efforts to tackle a pandemic.

For crisis response to be effective, policymakers need to pay particular attention to domestic investments and services, which continue to lag behind. Across India's states and union territories, therefore, there is a dire need for inter-sectoral, evidence-based response translating into knowledge-sharing practices and adaptive governance.

ANALYTICAL FRAMEWORK, METHODOLOGY AND DATA SOURCES FOR INDEXATION

a. Framework

The analytical framework of the study builds upon the development of the Health Systems Resilience Index across the 36 states and union territories. For this purpose, the quantified/ quantitative indicators reflecting each broad parameter/ sub-index under consideration are taken, and their respective weights in the context of the concerned sub-index are determined by principal component analysis. For this purpose, it is first necessary to apply transformation functions to the raw data. Subsequently, statistically computed weights and transformed indicator values are aggregated using the additive function to obtain the sub-index scores. Ghosh, et al (2014) suggest using Principal Component Analysis (PCA) for weight distribution since it stands out as one of the best practices globally, to enhance statistical robustness in assigning weights. Following this method, weights are attached to different indicators without exposing them to 'subjectivity' and 'sub-optimal representation'.

In the second round, using the sub-indices scores for all 36 states/UTs and weights assigned using informed arbitrariness, the composite scores for respective states have been arrived at. Assignment of weights for each sub-index has been driven by the objectives of our investigation- to simultaneously assess a state/UT's performance in terms of capacity building and capacity utilisation. Equal weight has been given to the domains capturing existing/additional resource bases and capacities, and the outcomes achieved through mobilising these resources.

At the first stage, the construction of the weighted sub-indices can, therefore, be represented by the following identity:

$$SI_{ij} = \sum_k w_{ki} \cdot X_{kij} \quad \text{--- (1)}$$

Where,

SI_{ij} is the score of the i^{th} sub – index for the j^{th} state/UT

w_{ki} is the weight of the k^{th} component indicator of the i^{th} sub – index obtained through principal component analysis over all indicators under this sub – index

X_{kij} is the normalised score of the k^{th} component indicator of the i^{th} sub – index for the j^{th} state/UT

In the next stage, using the respective sub-index scores, the Health Systems Resilience Index for each State/UT is estimated based on the following identity:

$$I_j = \sum_i w_i \cdot SI_{ij} \quad \text{--- -- -- (2)}$$

Where,

I_j is the composite score for the j^{th} state/UT

w_i is the weight of the i^{th} sub-index obtained through principal component analysis over all sub-index scores

SI_{ij} is the score of the i^{th} sub-index for the j^{th} state/UT

The states/UTs are then ranked based on their respective scores pertaining to each broad parameter/ sub-index as well as the comprehensive Health Systems Resilience Index, to assess their relative performance. Besides, a subsequent analysis between the states and the union territories, on the basis of their average performance, is carried out using a mean-difference test.

b. Indicators

For the purpose of computation of the proposed index, 33 component indicators were identified and grouped into 5 broad parameters (sub-index), namely, general health profile (4), medical infrastructure (11), technology infrastructure (3), institutional support (4) and COVID-19-related health outcomes (11). The latest available data for each variable were collected for each of the 20 large states, 8 small states and 8 union territories. Table A2 summarises the chosen indicators under each sub-index and the sources of data.

TABLE A2: INDICATORS OF HEALTH SYSTEMS RESILIENCE

Sub-Index	Indicator	Data Source
1. General Health Profile	1.1. Households with any usual member covered under a health insurance/financing scheme (%) ¹	NFHS 5 (2019)
	1.2. Children age 12-23 months fully vaccinated based on information from either vaccination card or mother's recall (%) ²	NFHS 5 (2019)
	1.3. Monthly per capita out-of-pocket expenditure on health as a share of Monthly Per capita Consumption Expenditure (%) ^{3,4,5}	SDG INDEX 2020, NITI Aayog, Government of India
	1.4. Prevalence of NCDs per 100,000 population ^{6,7}	Global Burden of Disease Study - India Compare (2019)
2. Medical Infrastructure	2.1. No. of Physicians, Nurses, midwives per 10,000 population ⁸	SDG 3 Index 2020, NITI Aayog, Government of India
	2.2. Registered Pharmacists in the State per 10,000 population ⁹	National Health Profile 2020
	2.3. COVID-19 Testing Labs per 10,000 population ¹⁰	
	2.4. COVID-19 Sample Collection Centres per 10,000 population ¹¹	ICMR, dated: 18 th August 2021
	2.5. Covid Beds per 10,000 population ^{12,13}	Various sources include state NHM/HFWD/COVID-19 Dashboards, dated: August 2021
	2.6. Dedicated Covid Hospitals (DCHs) per 10,000 population	Lok Sabha unstarred question no. 952, dated: 16 th September 2020
	2.7. Dedicated Covid Health Centre (DCHC) per 10,000 population	Lok Sabha unstarred question no. 952, dated: 16 th September 2020
	2.8. Dedicated Covid Care Centre (CCC) per 10,000 population	Lok Sabha unstarred question no. 952, dated: 16 th September 2020
	2.9. Vaccination Sites per 10,000 population ¹⁴	CoWIN DASHBOARD
	2.10. No. of Ventilators per 10,000 population ¹⁵	Rajya Sabha unstarred question no. 2518, dated: 5 th August 2021
	2.11. No. of blood banks per 10,000 population ^{16,17}	Lok Sabha starred question no. 173, dated: 30 th July 2021.

3. Technology Infrastructure	3.1. No. of mobile connections per 100 people ¹⁸	SDG Index 2020, NITI Aayog, Government of India
	3.2. No. of Internet Subscribers per 100 people ¹⁹	SDG Index 2020, NITI Aayog, Government of India
	3.3. Data Reporting Scores ^{20, 21, 22}	Various State Government Portals/Dashboards
4. Institutional Support ^{23, 24}	4.1. Revenue Expenditure (2. Medical and Public Health) per 10,000 population ²⁵	State Finances: Study of Budgets (2020), Reserve Bank of India
	4.2. Revenue Expenditure (3. Family Welfare) per 10,000 population ^{26, 27}	State Finances: Study of Budgets (2020), Reserve Bank of India
	4.3. Percentage change in revenue expenditure on health in 2020-21(RE) over 2019-20 (RE) ²⁸	State Finances: Study of Budgets (2020), Reserve Bank of India
	4.4. Percentage change in revenue expenditure on health in 2021-22(BE) over 2019-20 (RE) ^{29, 30}	State Finances: Study of Budgets (2020), Reserve Bank of India
5. COVID-19-related Health Outcomes	5.1. Vaccine Doses per 100,000 population ³¹	COVID19 BHARAT Dashboard, dated: 30 th November 2021
	5.2. Tests per 100,000 population ³²	COVID19 BHARAT Dashboard, dated: 30 th November 2021
	5.3. Deaths per 100,000 population ³³	COVID19 BHARAT Dashboard, dated: 15 th December 2021
	5.4. Cases per 100,000 population ³⁴	COVID19 BHARAT Dashboard, dated: 30 th November 2021
	5.5. Peak daily caseload per 100,000 population (7-day average) ³⁵	COVID19 BHARAT Dashboard, dated: 30 th November 2021
	5.6. Time taken between the highest peak of daily cases to its 20% (7-day average) ³⁶	COVID19 BHARAT Dashboard, dated: 30 th November 2021
	5.7. Time taken between peak positivity rate to fall below 5% (7-day average) ³⁷	COVID19 BHARAT Dashboard, dated: 30 th November 2021
	5.8. Distributional gap between highest and lowest vaccine coverage per 1000 population (district-wise) ^{38, 39, 40, 41}	CoWIN Dashboard, dated: 31 st October 2021
	5.9. Days taken to reach benchmark vaccination coverage of 18+ population ⁴²	COVID19 BHARAT Dashboard, dated: 30 th November 2021
	5.10. Weeks taken to reach benchmark vaccination coverage of 60+ population ⁴³	CoWIN Dashboard, dated: 30 th November 2021
	5.11. Gender gap in vaccination coverage (female-to-male ratio) per 18+ 100,000 population ⁴⁴	CoWIN Dashboard, dated: 30 th November 2021

c. Removing Scale Bias, Normalisation and Complement of Negative Indicators

The data collected across 36 Indian states and UTs, owing to the population size in most cases, has inherent scale biases. The variables have been converted into a per unit format (to remove the relevant scale bias). Further, all the data points were normalised by the following formula to range from 0 to 1 (unit free):

$$X_{kij} = \frac{x_{kij} - \min_j(x_{kij})}{\max_j(x_{kij}) - \min_j(x_{kij})} \quad \text{--- (3)}$$

Where,

X_{kij} is the normalised score of the k^{th} component indicator of the i^{th} sub – index for the j^{th} state/UT

x_{kij} is the value of the k^{th} component indicator of the i^{th} sub – index for the j^{th} state/UT

$\min_j(x_{kij})$ is the minimum value of the row vector of x_{kij} values across the States and UTs

$\max_j(x_{kij})$ is the maximum value of the row vector of x_{kij} values across the States and UTs

For the negative indicators (for example, prevalence of NCDs), the complement of 1 for their respective normalised values has been taken, so as to convert them into a positive indicator. This has been done to form a uniform, unit and direction-free, composite preparedness index.

d. Determination of Weights by Principal Component Analysis and Informed Arbitrariness (Nested Weights)

In the first stage, calculation of weights for each indicator under a particular sub-index (or, parameter), for 36 observations have been conducted by Principal Component Analysis (PCA) to rank the states/UTs under each sub-index (See Annexure III Charts A1.1 – A5.3). This methodology has been chosen over a simple average technique to understand the dominant patterns in the dataset, in terms of weights that should be assigned to each parameter. With 'i' denoting sub-index (parameter), the 5 sub-indices are defined by the closed set, $i = [1, 5]$. At the same time, k denoting a component indicator, the indicators are determined by the closed set $k = [1, 33]$.

Now let us define the weight attached, by PCA, to an indicator 'm' in sub-index 'n' as w_{mn} where,

$$w_{mn} = [\max\{comp1, \dots, compm\}]^2 * \text{explanatory power of } [\max\{comp1, \dots, compm\}].$$

Each of the weights under a particular sub-index has been scaled, to sum up to 1 (100%) in order to avoid under-representation.^{46,47,48} Finally, we get the state/UT and sub-index-wise scores as given in (1).

FIGURE A1: WEIGHTS ASSIGNED TO COMPONENT INDICATORS USING PRINCIPAL COMPONENT ANALYSIS

General Health Profile	Medical Infrastructure	Technology Infrastructure	Institutional Support	Covid-19 related Health Outcomes
<ul style="list-style-type: none"> • Health Insurance coverage (17 %) • Fully vaccinated children in the state (30 %) • Monthly per capita out-of-pocket expenditure as a share of per capita Consumption Expenditure (45%) • Prevalence of NCDs –Diabetes & Kidney Diseases, Neoplasms (Cancer), Respiratory Infections & TB, Cardiovascular Diseases (8 %) 	<ul style="list-style-type: none"> • No. of Physicians/ Nurses/Midwives (7 %) • Registered Pharmacists (10 %) • Covid-19 Sample Collection Centres (9 %) • Covid-19 Testing Labs (12 %) • Dedicated Covid-19 Beds (6 %) • Dedicated Covid-19 Hospital (9 %) • Dedicated Covid-19 Health Centres (12 %) • Dedicated Covid-19 Care Centres (10 %) • Covid-19 Vaccination sites (4 %) • No. of ventilators (11 %) • No. of blood banks (10 %) 	<ul style="list-style-type: none"> • No. of Mobile Connections (32 %) • No. of Internet Subscribers (33 %) • Data Reporting & Granularity (35 %) 	<ul style="list-style-type: none"> • Revenue Expenditure (Medical and Public Health) per 10,000 population (RE 2020-21) (24 %) • Revenue Expenditure (Family Welfare) per 10,000 population (RE 2020-21) (25 %) • % Change in revenue expenditure on health in 2020-21(RE) over 2019-20 (RE) (26 %) • % Change in revenue expenditure on health in 2021-22(BE) over 2019-20 (RE) (25 %) 	<ul style="list-style-type: none"> • Vaccine doses administered (11 %) • Tests conducted (11 %) • Reported Cases (1 %) • Reported Deaths (4 %) • Peak daily caseload per 100,000 population (7-day avg.) Next, the corresponding weight for each of the 5 sub-indices has been assigned using informed arbitrariness. Equal weight has been assigned to the existing/ additional resource base/ capacities captured through the general health profile, medical and technology infrastructure, as well as institutional support, and the outcomes achieved through mobilisation of these resources are reflected in the COVID-19-related health outcomes across the various states and UTs. Using the weights for each sub-index 'n', we calculate the composite Health Systems Resilience Index as defined in (2) to rank the states and union territories in terms of their preparedness (See Annexure III: Charts A6.1 – A6.3).

FIGURE A2: WEIGHTS ASSIGNED TO COMPONENT SUB-INDICES USING INFORMED ARBITRARINESS

Weights (Informed Arbitrariness)
<ul style="list-style-type: none">• General Health Profile (12.5 %)• Medical Infrastructure (12.5 %)• Technology Infrastructure (12.5 %)• Institutional Support (12.5 %)• COVID-19 related Health Outcomes (50 %)

ANNEXURE IV: COMPARISON BETWEEN AVERAGE PERFORMANCE OF STATES AND UNION TERRITORIES
TABLE A3: RESULTS FOR MEAN-DIFFERENCE TEST (T-TEST) BETWEEN STATES AND UNION TERRITORIES

t-test	Health Systems Resilience Index	
sample mean_Small states	m1	0.47
sample mean_Large states	m2	0.44
t-statistic	T	1.03
p-value		0.16
Null hypothesis	$m1 = m2$	There is no significant difference in the average performance of small states and large states
Alternate hypothesis	$m1 > m2$	The average performance of small states is significantly better than the large states
Inference (at 5% significance level)	Null hypothesis cannot be rejected.	The difference in mean values is not statistically significant.

TABLE A4: RESULTS FOR MEAN-DIFFERENCE TEST (T-TEST) BETWEEN STATES AND UNION TERRITORIES

t-test	Health Systems Resilience Index	
sample mean_UTs	m1	0.54
sample mean_States	m2	0.45
t-statistic	T	3.11
p-value		0.00
Null hypothesis	$m1 = m2$	There is no significant difference in the average performance of states, and UTs
Alternate hypothesis	$m1 > m2$	The average performance of UTs is significantly better than the States
Inference (at 5% significance level)	Null hypothesis is rejected.	The difference in mean values is statistically significant at a 1% level of significance.

ANNEXURE V: PER CAPITA NSDP AND HEALTH SYSTEMS RESILIENCE OF THE STATES AND UTS
TABLE A5: RESULTS FOR CORRELATION (F-TEST) BETWEEN PER CAPITA NSDP AND HEALTH SYSTEMS RESILIENCE INDEX⁴⁹

Variables	X	Per Capita Net State Domestic Product
	Y	Health Systems Resilience Index
Correlation Coefficient	R	0.63
R-squared	R ²	0.40
p-value		0.00
Null hypothesis	R = 0	X and Y are uncorrelated
Alternate hypothesis	R ≠ 0	X and Y are correlated
Inference (at 1% significance level)	Null hypothesis is rejected. The correlation between X and Y is statistically significant at 1% level of significance.	

-
- 1 The actual values were expressed in percentage (%), normalized on a scale of 0 to 1.
 - 2 The actual values were expressed in percentage (%), normalized on a scale of 0 to 1.
 - 3 Only upward deviations from the threshold value of 10% monthly per capita out-of-pocket health expenditure as a share of per capita consumption expenditure have been considered as an indicator of household financial stress. All negative deviations have been set to 0.
 - 4 For Sikkim, the missing data has been substituted using the average value for the North-East region.
 - 5 The deviation values were expressed in percentage (%), normalized on a scale of 0 to 1. The normalised values have been subtracted from 1 to convert into its complement.
 - 6 For the indicator (or, variable) prevalence of non-communicable diseases (NCDs), four most common diseases, namely, diabetes and kidney diseases, neoplasm, respiratory infection and TB and cardiovascular diseases, were identified and their respective normalised scores were added up to arrive at the final figures for the indicator. The normalised values have been subtracted from 1 to convert into its complement.
 - 7 Data for J&K and Ladakh are reported together; the study reports a category of "Other Union Territories", whose value has been used for D&D and D&NH, Andaman & Nicobar, Chandigarh, Puducherry and Lakshadweep.
 - 8 The original values were normalized on a scale of 0 to 1. In case of missing data for Andaman & Nicobar Islands, Lakshadweep, Puducherry and Daman& Diu and Dadra & Nagar Haveli, corresponding regional averages have been used as substitutes.
 - 9 The original values were normalized on a scale of 0 to 1. In case of missing data for Jammu & Kashmir, Ladakh, Andaman & Nicobar Islands and Lakshadweep, corresponding regional averages have been used as substitutes.
 - 10 The data includes both government and private institutions. The original values were normalized on a scale of 0 to 1.
 - 11 The data includes both government and private institutions. The original values were normalized on a scale of 0 to 1.
 - 12 Numbers of beds imply total number of Isolation beds, Oxygen beds and ICU beds. The original values were normalized on a scale of 0 to 1.
 - 13 In case of missing data for Jammu & Kashmir, Sikkim and Lakshadweep, corresponding regional averages have been used as substitutes.
 - 14 The data includes both government and private institutions. The original values were normalized on a scale of 0 to 1.
 - 15 Only government data, private data is not recorded centrally. The original values were normalized on a scale of 0 to 1.
 - 16 The original values were normalized on a scale of 0 to 1.
 - 17 In case of missing data for Ladakh, corresponding regional average has been used as a substitute.
 - 18 The original values were normalized on a scale of 0 to 1.
 - 19 In case of missing data for Chandigarh, Andaman & Nicobar Islands, Lakshadweep, Puducherry and

Daman& Diu and Dadra & Nagar Haveli, corresponding regional averages have been used as substitutes. The original values were normalized on a scale of 0 to 1.

20 This is based on composite scoring of data availability, accessibility and granularity across state portals and social media, relating to COVID-19 and includes variables such as:

Gender and age segregated data reporting for COVID-19 related cases and deaths. Chandigarh, Manipur, Karnataka (Deaths), Tamil Nadu (Deaths) report gender-segregated data in daily bulletins only. Split in cumulative cases wasn't found.

Dedicated COVID-19 Website reporting real-time (updated every 24-48 hours) and historical (at least past 1 month data is easily accessible to public use) data.

Real-time data for Beds/Hospitals implies updated within the past 7 days.

Social Media platforms have been verified to update at least every 24 hours with COVID-19 update.

Availability of state bulletins in English language.

21 For qualitative indicators pertaining to data reporting scores, 0-1 dummy variables were used for scoring and aggregated to arrive at a total score for each state/UT, to be utilised in subsequent stages of computation.

22 For Andhra Pradesh, finer details on data segregation could not be studied as the bulletins are in Telugu only. The score used here have been taken from a previous study available at: https://github.com/varunvasudevan/CDRS-India/blob/master/study3_june_2021/surveillance_reporting.csv#L29(updated June 2021).

23 In case of missing data for Chandigarh, Ladakh, Andaman & Nicobar Islands, Lakshadweep, Daman& Diu and Dadra & Nagar Haveli, corresponding regional averages have been used as substitutes. The final scores were normalized on a scale of 0 to 1.

24 The Ayushman Bharat- PMJAY scheme covering upto INR 5 lakhs of medical costs of treatment as Insurance was considered to be a good indicator of State Government's response to COVID-19. But the data on the percentage coverage of the COVID-19 claims issued w.r.t. the claims filed was unavailable in the public domain. While attempts were made to procure this data from the authorities, it wasn't collected centrally.

25 The original values were normalized on a scale of 0 to 1.

26 Two separate indicators have been considered to account for revenue expenditure in the health sector – current provisioning and future potential. Expenditure on family health and welfare, in addition to targeted provision of maternity and child healthcare services, includes expenditure on mass education, research and evaluation of the existing structure which bear implications for the future potential of the system.

27 The original values were normalized on a scale of 0 to 1.

28 The original values were normalized on a scale of 0 to 1.

29 The percentage change in revenue expenditure on health for 2021-2022(BE) has been calculated considering 2019-20 as the base year for a comparison to the "business as usual" scenario.

30 The original values were normalized on a scale of 0 to 1.

31 The original values were normalized on a scale of 0 to 1.

32 The original values were normalized on a scale of 0 to 1.

33 For the indicator on COVID-19-related deaths, a later cut-off date has been referred to account for backlogs in the number of deaths reported at any given time. The original values were normalized on a

scale of 0 to 1. The normalised values have been subtracted from 1 to convert into its complement.

34 The original values were normalized on a scale of 0 to 1. The normalised values have been subtracted from 1 to convert into its complement.

35 The original values were normalized on a scale of 0 to 1. The normalised values have been subtracted from 1 to convert into its complement.

36 The original values were normalized on a scale of 0 to 1. The normalised values have been subtracted from 1 to convert into its complement.

37 For states/UTs like Dadra & Nagar Haveli and Daman & Diu, Telangana, Lakshadweep, Mizoram, Ladakh and Delhi consistent time series data on testing/positivity rate were not available. Hence, corresponding missing values were substituted with regional averages. The original values were normalized on a scale of 0 to 1. The normalised values have been subtracted from 1 to convert into its complement.

38 Total district-wise vaccination doses were used to calculate corresponding vaccination coverage of eligible population (18+ years population) for each district, using population estimates from the Periodic Labour Force Survey (PLFS) (2017-18).

39 For some newly formed districts/otherwise cases where PLFS population figures were not available, district level 18+ population was estimated using average regional population density and total area covered by the district (sourced from various district administration websites).

Exceptions: a) For Delhi, average population density across all districts is used for estimation of eligible population for districts with missing values.

b) For Noney district in Manipur, the total population figure available at <https://geoiq.io/places/Noney/SiuzoWJoO1> was used for estimation of eligible population.

40 For distributional gap estimation, the range between the best and the worst performing district in each state with respect to vaccination coverage has been calculated. Standard deviation has not been used since it measures the disparity w.r.t. the mean performer and would, hence, iron out the absolute disparity, to some extent.

41 The original values were normalized on a scale of 0 to 1. The normalised values have been subtracted from 1 to convert into its complement.

42 Jharkhand had the lowest vaccination coverage as of 30th November 2021, which has been considered as the benchmark for comparison. The original values were normalized on a scale of 0 to 1. The normalised values have been subtracted from 1 to convert into its complement.

43 The indicator on vaccine coverage among 60+ populations has been included to separately account for access among priority groups. Jharkhand and Tamil Nadu had the lowest vaccination coverage as of the week of 30th November 2021, which has been considered as the benchmark for comparison. The original values were normalized on a scale of 0 to 1. The normalised values have been subtracted from 1 to convert into its complement.

44 The indicator on gender gap in vaccine coverage has been included to account for the already known barriers in accessing healthcare services. This is a sensitive indicator used to assess gendered access to healthcare services. The female-to-male ratio in vaccine coverage was normalized on a scale of 0 to 1. While the access to medical services is believed to be further disadvantageous for gender and sexual minorities such as the LGBTQ+ groups, lack of data is a pertinent limitation in studying it.

⁴⁵ All computations have been done on STATA 14.0.

⁴⁶ Under General Health Profile, the “Prevalence of NCDs” has been considered a relevant indicator-capturing the intrinsic risks of comorbidity associated with the population of a state. However, since it is not a direct policy tool at the hands of the states/UTs, it has a relatively lower weight (8%) compared to other relevant indicators considered under this domain.

⁴⁷ Under Medical Infrastructure, the “Total number of vaccination sites” – while a relevant indicator of state capacity- does not capture complementary efforts of vaccinations such as door-to-door campaigns, temporary camps, etc. Accordingly, this indicator has a relatively low weight, i.e., 4%. However, the missing information in this regard has been somewhat captured through the indicators on vaccination coverage included under COVID-19-related Health Outcomes.

⁴⁸ Under COVID-19-related Health Outcomes, both input (related to tests and vaccination) and output (related to direct health outcomes such as deaths, cases, rate of infection) variables have been considered.

The indicators on “Cumulative deaths”, “Cumulative cases” and the “Peak caseload” have relatively low weights (4%, 1% and 3%, respectively) among the output variables – since, they are significantly sensitive to reporting. For example, the definition of COVID-19-related deaths varies considerably across states.

The two indicators “Days taken between the highest peak of daily cases to its 20%” and “Time taken between peak positivity rate to fall below 5%” capture a state’s performance relative to its’ own reporting. While these are partially correlated, they capture significant amount of unique information. For example, a state may bring down its daily number of cases faster simply by testing less (without any actual decrease), in which case the positivity rate will increase, or vice-versa. Hence, these two indicators have been considered as complementary sets of information, not substitutes.

⁴⁹ Data on per capita Net State Domestic Products (current prices) (2018-19) has been sourced from National Statistical Office, Ministry of Statistics and Programme Implementation, Government of India. The union territories of Andaman & Nicobar, Dadra & Nagar Haveli and Daman & Diu, Lakshadweep, and Ladakh have not been considered for the calculation of correlation coefficient due to unavailability of corresponding NSDP figures.

About the Authors

Mona is a Junior Fellow with ORF's Health Initiative. She has been tracking COVID-19 analytics extensively while studying its impact on populations globally. Her research expertise and interests lie broadly at the intersection of public health, gender, and social policy. She is a post-graduate from the Tata Institute of Social Sciences.

Debosmita Sarkar is a Junior Fellow with ORF's Centre for New Economic Diplomacy, and a graduate student at the Centre for Economic Studies and Planning, Jawaharlal Nehru University. She completed her Master's degree in Economics from JNU. She was awarded the Global Partnerships Network MA Scholarship in 2021.

Soumya Bhowmick is an Associate Fellow at ORF's Centre for New Economic Diplomacy. Soumya holds a double Master's degree in Economics from Jadavpur University, Kolkata and the University of Antwerp, Belgium (with a specialisation in Economics of Globalisation and European Integration). He has been awarded the Government of Japan's JASSO Scholarship, Tokyo Foundation's SYLFF Fellowship, and the European Commission's EMJMD Fellowship.

Renita D'Souza is a PhD in Economics and a Fellow at ORF, Mumbai, under the Inclusive Growth and SDGs programme. Her research focuses on development economics, including environmental and development finance; sustainability issues such as poverty, climate change, resource efficiency; and the Indian economy. Her expertise is in quantitative economics and statistical modelling.

Nilanjan Ghosh is Director of ORF's Centre for New Economic Diplomacy, and ORF's Kolkata Centre. His previous positions include Senior Fellow and Head of Economics at ORF Kolkata; Senior Vice President & Chief Economist at MCX (I) Limited in Mumbai; and Professor of Econometrics at the TERI School of Advanced Studies in New Delhi.

Oommen C. Kurian is a Senior Fellow and Head of ORF's Health Initiative. He studies India's health sector reforms within the broad context of the Sustainable Development Goals, with a focus on financing and governance structures. Oommen is a member of the India Task Force of the Lancet Covid-19 Commission.

Authors' Note

This project has been extremely challenging and yet a most enriching experience for the entire research team. The authors thank Dr. Samir Saran, President of ORF and Dr. Shamika Ravi, Vice President at ORF, for their valuable feedback which helped us complete this research and give the report its singular voice.

We also thank the anonymous reviewers of the report who provided valuable feedback on a previous draft of this report.
